Chapter 3

Data Structure Documentation

3.1 AEdge Class Reference

Public Member Functions

• AEdge (int n0, int l0, int n1, int l1)

Data Fields

- ECand * cand
- int **nodes** [2]
- int **nlegs** [2]
- int ptcl
- int **DUMMYPADDING**

3.1.1 Detailed Description

Definition at line 1102 of file grcc.h.

The documentation for this class was generated from the following file:

· grcc.h

3.2 AllGlobals Struct Reference

#include <structs.h>

Public Member Functions

PADPOSITION (0, 0, 0, 0, sizeof(struct P_const)+sizeof(struct T_const)+sizeof(struct X_const))

- struct M_const M
- struct C_const Cc
- struct S const S
- struct R_const R
- struct N_const N
- struct O_const O
- struct P_const P
- struct T const T
- struct X_const X

3.2.1 Detailed Description

Without pthreads (FORM) the ALLGLOBALS struct has all the global variables

Definition at line 2614 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.3 ANode Class Reference

Public Member Functions

- ANode (int dg)
- int **newleg** (void)

Data Fields

- int deg
- int nlegs
- int * anodes
- int * aedges
- int * aelegs
- NCand * cand

3.3.1 Detailed Description

Definition at line 1078 of file grcc.h.

The documentation for this class was generated from the following file:

• grcc.h

3.4 ARGBUFFER Struct Reference

Data Fields

- WORD * buffer
- DOLLARS dollar
- · LONG size
- · int type
- int dummy

3.4.1 Detailed Description

Definition at line 601 of file ratio.c.

The documentation for this struct was generated from the following file:

· ratio.c

3.5 Assign Class Reference

Public Member Functions

- Assign (SProcess *sprc, MGraph *mgr, PNodeClass *pnc)
- void prCand (const char *msg)
- void checkAG (const char *msg)
- Bool assignAllVertices (void)
- Bool selectVertex (void)
- Bool selectVertexSimp (int lastv)
- Bool **selectLeg** (int v, int lastlg)
- Bool assignVertex (int v)
- Bool allAssigned (void)

 Beat from MO and by (void)
- Bool fromMGraph (void)
- void addEdge (int n0, int n1, int nplist, int *plist)
- void **connect** (int n0, int l0, int eg, int el, int n1, int l1)
- Bool fillEGraph (int aid, BigInt nsym, BigInt esym, BigInt nsym1)
- int * reordLeg (int n, int *reord, int *plist, int *used)
- int getLegParticle (int n, int ln)
- int legEdgeParticle (int n, int ln, int pt)
- int legPart (int v, int lg, int nplst, int *plst, int *rlist, const int size)
- int candPart (int v, int ln, int *plist, const int size)
- int selUnAssVertex (void)
- int selUnAssVertexSimp (int lastv)
- int selUnAssLeg (int v, int lastlg)
- NCandSt assignIVertex (int v, int ia)
- Bool assignPLeg (int n, int In, int pt)
- Bool isOrdPLeg (int n, int ln, int pt)
- Bool detEdge (int e)
- Bool candPartClassify (int v, int *npdass, int *pdass, int *ppuass, int *ppuass, const int size)
- Bool updateCandNode (int v)
- Bool checkOrderCpl (void)
- Bool isOrdLegs (void)
- Bool islsomorphic (MNodeClass *cl, BigInt *nsym, BigInt *esym, BigInt *nsym1)
- int cmpPermGraph (int *p, MNodeClass *cl)
- int cmpNodes (int nd0, int nd1, MNodeClass *cn)
- BigInt edgeSym (void)
- void saveCouple (int *sav)
- void restoreCouple (int *sav)
- Bool subCouple (int *cpl)

- EGraph * egraph
- MGraph * mgraph
- SProcess * sproc
- Process * proc
- Model * model
- Options * opt
- AStack * astack
- PNodeClass * pnclass
- MOrbits * orbits
- int nNodes
- · int nEdges
- int nExtern
- · int nETotal
- · BigInt nAGraphs
- Fraction wAGraphs
- BigInt nAOPI
- Fraction wAOPI
- ANode ** nodes
- AEdge ** edges
- CheckPt checkpoint0
- int cplleft [GRCC_MAXNCPLG]

3.5.1 Detailed Description

Definition at line 1121 of file grcc.h.

The documentation for this class was generated from the following file:

• grcc.h

3.6 AStack Class Reference

Public Member Functions

- · AStack (int nSize, int eSize)
- void setAGraph (Assign *ag)
- void checkPoint (CheckPt sav)
- void restore (CheckPt sav)
- void restoreMsg (CheckPt sav, const char *msg)
- void prStack (void)
- void pushNode (int n)
- void **pushEdge** (int e)

Data Fields

- Assign * agraph
- NStack ** nStack
- · int nStackP
- int nSize
- EStack ** eStack
- · int eStackP
- · int eSize

3.6.1 Detailed Description

Definition at line 1305 of file grcc.h.

The documentation for this class was generated from the following file:

• grcc.h

3.7 bit_field Struct Reference

```
#include <structs.h>
```

Data Fields

- UBYTE bit 0: 1
- UBYTE bit_1: 1
- UBYTE bit 2: 1
- UBYTE **bit_3**: 1
- UBYTE bit_4: 1
- UBYTE bit_5: 1
- UBYTE bit_6: 1
- UBYTE bit 7: 1

3.7.1 Detailed Description

The struct bit_field is used by set_in, set_set, set_del and set_sub. They in turn are used in pre.c to toggle bits that indicate whether a character can be used as a separator of function arguments. This facility is used in the communication with external channels.

Definition at line 927 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.8 BrAcKeTiNdEx Struct Reference

Public Member Functions

• **PADPOSITION** (0, 2, 0, 0, 0)

Data Fields

- POSITION start
- POSITION next
- · LONG bracket
- · LONG termsinbracket

3.8.1 Detailed Description

Definition at line 317 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.9 BracketInfo Struct Reference

Public Member Functions

- BracketInfo (const std::vector< int > &pattern, int num_terms, const poly *p)
- bool operator< (const BracketInfo &rhs) const

Data Fields

- std::vector< int > pattern
- int num_terms
- int dummy
- const poly * p

3.9.1 Detailed Description

Definition at line 1389 of file polygcd.cc.

The documentation for this struct was generated from the following file:

• polygcd.cc

3.10 BrAcKeTiNfO Struct Reference

Data Fields

- BRACKETINDEX * indexbuffer
- WORD * bracketbuffer
- · LONG bracketbuffersize
- · LONG indexbuffersize
- LONG bracketfill
- · LONG indexfill
- WORD SortType

3.10.1 Detailed Description

Definition at line 329 of file structs.h.

3.10.2 Field Documentation

3.10.2.1 indexbuffer

BRACKETINDEX* BrAckeTiNfO::indexbuffer

[D]

Definition at line 330 of file structs.h.

3.10.2.2 bracketbuffer

WORD* BrAcKeTiNfO::bracketbuffer

[D]

Definition at line 331 of file structs.h.

3.10.2.3 SortType

WORD BrAcKeTiNfO::SortType

The sorting criterium used (like POWERFIRST etc)

Definition at line 336 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.11 buflPstruct Struct Reference

Data Fields

- LONG i
- struct ExPrEsSiOn e

3.11.1 Detailed Description

Definition at line 3910 of file parallel.c.

The documentation for this struct was generated from the following file:

parallel.c

3.12 C const Struct Reference

3.12.1 Detailed Description

The C_const struct is part of the global data and resides in the ALLGLOBALS struct #A under the name #C. We see it used with the macro #AC as in AC.exprnames. It contains variables that involve the compiler and objects set during compilation.

Definition at line 1698 of file structs.h.

3.12.2 Field Documentation

3.12.2.1 separators

```
set_of_char C_const::separators
```

Separators in #call and #do

Definition at line 1699 of file structs.h.

3.12.2.2 dollarnames

```
NAMETREE* C_const::dollarnames
```

[D] Names of dollar variables

Definition at line 1701 of file structs.h.

3.12.2.3 exprnames

```
NAMETREE* C_const::exprnames
```

[D] Names of expressions

Definition at line 1702 of file structs.h.

3.12.2.4 varnames

```
NAMETREE* C_const::varnames
```

[D] Names of regular variables

Definition at line 1703 of file structs.h.

3.12.2.5 ChannelList

```
LIST C_const::ChannelList
```

Used for the #write statement. Contains CHANNEL

Definition at line 1704 of file structs.h.

3.12.2.6 DubiousList

```
LIST C_const::DubiousList
```

List of dubious variables. Contains #DUBIOUSV. If not empty -> no execution

Definition at line 1706 of file structs.h.

3.12.2.7 FunctionList

```
LIST C_const::FunctionList
```

List of functions and properties. Contains FUNCTIONS

Definition at line 1708 of file structs.h.

3.12.2.8 ExpressionList

```
LIST C_const::ExpressionList
```

List of expressions, locations etc.

Definition at line 1709 of file structs.h.

3.12.2.9 IndexList

```
LIST C_const::IndexList
```

List of indices

Definition at line 1710 of file structs.h.

3.12.2.10 SetElementList

```
LIST C_const::SetElementList
```

List of all elements of all sets

Definition at line 1711 of file structs.h.

3.12.2.11 SetList

```
LIST C_const::SetList
```

List of the sets

Definition at line 1712 of file structs.h.

3.12.2.12 SymbolList

```
LIST C_const::SymbolList
```

List of the symbols and their properties

Definition at line 1713 of file structs.h.

3.12.2.13 VectorList

```
LIST C_const::VectorList
```

List of the vectors

Definition at line 1714 of file structs.h.

3.12.2.14 PotModDolList

```
LIST C_const::PotModDolList
```

Potentially changed dollars

Definition at line 1715 of file structs.h.

3.12.2.15 ModOptDolList

LIST C_const::ModOptDolList

Module Option Dollars list

Definition at line 1716 of file structs.h.

3.12.2.16 TableBaseList

LIST C_const::TableBaseList

TableBase list

Definition at line 1717 of file structs.h.

3.12.2.17 cbufList

LIST C_const::cbufList

List of compiler buffers

Definition at line 1721 of file structs.h.

3.12.2.18 autonames

NAMETREE* C_const::autonames

[D] Names in autodeclare

Definition at line 1729 of file structs.h.

3.12.2.19 Streams

STREAM* C_const::Streams

(C) Pointer for AutoDeclare statement. Points either to varnames or autonames. [D] The input streams.

Definition at line 1738 of file structs.h.

3.12.2.20 CurrentStream

```
STREAM* C_const::CurrentStream
```

(C) The current input stream. Streams are: do loop, file, prevariable. points into Streams memory.

Definition at line 1739 of file structs.h.

3.12.2.21 termstack

```
LONG* C_const::termstack
```

[D] Last term statement {offset}

Definition at line 1744 of file structs.h.

3.12.2.22 termsortstack

```
LONG* C_const::termsortstack
```

[D] Last sort statement {offset}

Definition at line 1745 of file structs.h.

3.12.2.23 cmod

```
UWORD* C_const::cmod
```

[D] Local setting of modulus. Pointer to value.

Definition at line 1746 of file structs.h.

3.12.2.24 powmod

```
UWORD* C_const::powmod
```

Local setting printing as powers. Points into cmod memory

Definition at line 1747 of file structs.h.

3.12.2.25 modpowers

UWORD* C_const::modpowers

[D] The conversion table for mod-> powers.

Definition at line 1748 of file structs.h.

3.12.2.26 IfHeap

LONG* C_const::IfHeap

[D] Keeps track of where to go in if

Definition at line 1752 of file structs.h.

3.12.2.27 IfCount

LONG* C_const::IfCount

[D] Keeps track of where to go in if

Definition at line 1753 of file structs.h.

3.12.2.28 IfStack

LONG* C_const::IfStack

Keeps track of where to go in if. Points into IfHeap-memory

Definition at line 1754 of file structs.h.

3.12.2.29 iBuffer

UBYTE* C_const::iBuffer

[D] Compiler input buffer

Definition at line 1755 of file structs.h.

3.12.2.30 iPointer

UBYTE* C_const::iPointer

Running pointer in the compiler input buffer

Definition at line 1756 of file structs.h.

3.12.2.31 iStop

UBYTE* C_const::iStop

Top of iBuffer

Definition at line 1757 of file structs.h.

3.12.2.32 LabelNames

UBYTE** C_const::LabelNames

[D] List of names in label statements

Definition at line 1758 of file structs.h.

3.12.2.33 FixIndices

WORD* C_const::FixIndices

[D] Buffer of fixed indices

Definition at line 1759 of file structs.h.

3.12.2.34 termsumcheck

WORD* C_const::termsumcheck

[D] Checking of nesting

Definition at line 1760 of file structs.h.

3.12.2.35 WildcardNames

UBYTE* C_const::WildcardNames

[D] Names of ?a variables

Definition at line 1761 of file structs.h.

3.12.2.36 Labels

int* C_const::Labels

Label information for during run. Pointer into LabelNames memory.

Definition at line 1762 of file structs.h.

3.12.2.37 tokens

SBYTE* C_const::tokens

[D] Array with tokens for tokenizer

Definition at line 1763 of file structs.h.

3.12.2.38 toptokens

SBYTE* C_const::toptokens

Top of tokens

Definition at line 1764 of file structs.h.

3.12.2.39 endoftokens

SBYTE* C_const::endoftokens

End of the actual tokens

Definition at line 1765 of file structs.h.

3.12.2.40 tokenarglevel

WORD* C_const::tokenarglevel

[D] Keeps track of function arguments

Definition at line 1766 of file structs.h.

3.12.2.41 CheckpointRunAfter

char* C_const::CheckpointRunAfter

[D] Filename of script to be executed before creating the snapshot. =0 if no script shall be executed.

Definition at line 1773 of file structs.h.

3.12.2.42 CheckpointRunBefore

char* C_const::CheckpointRunBefore

[D] Filename of script to be executed after having created the snapshot. =0 if no script shall be executed.

Definition at line 1775 of file structs.h.

3.12.2.43 IfSumCheck

 ${\tt WORD*\ C_const::} {\tt IfSumCheck}$

[D] Keeps track of if-nesting

Definition at line 1777 of file structs.h.

3.12.2.44 CheckpointStamp

LONG C_const::CheckpointStamp

Timestamp of the last created snapshot (set to Timer(0)).

Definition at line 1797 of file structs.h.

3.13 CbUf Struct Reference 27

3.12.2.45 CheckpointInterval

LONG C_const::CheckpointInterval

Time interval in milliseconds for snapshots. =0 if snapshots shall be created at the end of *every* module.

Definition at line 1798 of file structs.h.

3.12.2.46 cbufnum

int C_const::cbufnum

Current compiler buffer

Definition at line 1806 of file structs.h.

3.12.2.47 NoShowInput

int C_const::NoShowInput

(C) Mode of looking for names. Set to NOAUTO (=0) or WITHAUTO (=2), cf. AutoDeclare statement

Definition at line 1809 of file structs.h.

3.12.2.48 CheckpointFlag

int C_const::CheckpointFlag

Tells preprocessor whether checkpoint code must executed. -1 : do recovery from snapshot, set by command line option; 0 : do nothing; 1 : create snapshots, set by On checkpoint statement

Definition at line 1873 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.13.1 Detailed Description

The CBUF struct is used by the compiler. It is a compiler buffer of which since version 3.0 there can be many.

Definition at line 992 of file structs.h.

3.13.2 Field Documentation

3.13.2.1 Buffer

WORD* CbUf::Buffer

[D] Size in BufferSize

Definition at line 993 of file structs.h.

3.13.2.2 Top

WORD* CbUf::Top

pointer to the end of the Buffer memory

Definition at line 994 of file structs.h.

3.13 CbUf Struct Reference 29

3.13.2.3 Pointer

WORD* CbUf::Pointer

pointer into the Buffer memory

Definition at line 995 of file structs.h.

3.13.2.4 lhs

WORD** CbUf::lhs

[D] Size in maxlhs. list of pointers into Buffer.

Definition at line 996 of file structs.h.

3.13.2.5 rhs

WORD** CbUf::rhs

[D] Size in maxrhs. list of pointers into Buffer.

Definition at line 997 of file structs.h.

3.13.2.6 CanCommu

LONG* CbUf::CanCommu

points into rhs memory behind WORD* area.

Definition at line 998 of file structs.h.

3.13.2.7 NumTerms

LONG* CbUf::NumTerms

points into rhs memory behind CanCommu area

Definition at line 999 of file structs.h.

3.13.2.8 numdum

WORD* CbUf::numdum

points into rhs memory behind NumTerms

Definition at line 1000 of file structs.h.

3.13.2.9 dimension

WORD* CbUf::dimension

points into rhs memory behind numdum

Definition at line 1001 of file structs.h.

3.13.2.10 boomlijst

COMPTREE* CbUf::boomlijst

[D] Number elements in MaxTreeSize

Definition at line 1002 of file structs.h.

3.13.2.11 BufferSize

LONG CbUf::BufferSize

Number of allocated WORD's in Buffer

Definition at line 1003 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.14 ChAnNeL Struct Reference

#include <structs.h>

- char * name
- · int handle

3.14.1 Detailed Description

When we read input from text files we have to remember not only their handle but also their name. This is needed for error messages. Hence we call such a file a channel and reserve a struct of type CHANNEL to allow to lay this link.

Definition at line 1023 of file structs.h.

3.14.2 Field Documentation

3.14.2.1 name

char* ChAnNeL::name

[D] Name of the channel

Definition at line 1024 of file structs.h.

3.14.2.2 handle

int ChAnNeL::handle

File handle

Definition at line 1025 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.15 COST Struct Reference

Data Fields

- LONG add
- LONG mul
- · LONG div
- LONG pow

3.15.1 Detailed Description

Definition at line 1295 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.16 CSEEq Struct Reference

Public Member Functions

• bool operator() (const vector< WORD > &lhs, const vector< WORD > &rhs) const

3.16.1 Detailed Description

3.25 DoLIArS Struct Reference

Data Fields

- WORD * where
- FACDOLLAR * factors
- LONG size
- · LONG name
- WORD type
- WORD node
- WORD index
- WORD zero
- WORD numdummies
- WORD nfactors

3.25.1 Detailed Description

Definition at line 530 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.26 DoLoOp Struct Reference

#include <structs.h>

- PRELOAD p
- UBYTE * name
- UBYTE * vars
- UBYTE * contents
- UBYTE * dollarname
- · LONG startlinenumber
- · LONG firstnum
- · LONG lastnum
- LONG incnum
- · int type
- int NoShowInput
- int errorsinloop
- · int firstloopcall
- WORD firstdollar
- · WORD lastdollar
- · WORD incdollar
- WORD NumPreTypes
- WORD PrelfLevel
- WORD PreSwitchLevel

3.26.1 Detailed Description

Each preprocessor do loop has a struct of type DOLOOP to keep track of all relevant parameters like where the beginning of the loop is, what the boundaries, increment and value of the loop parameter are, etc. Also we keep the whole loop inside a buffer of type PRELOAD

Definition at line 897 of file structs.h.

3.26.2 Field Documentation

3.26.2.1 p

PRELOAD DoLoOp::p

size, name and buffer

Definition at line 898 of file structs.h.

3.26.2.2 name

UBYTE* DoLoOp::name

pointer into PRELOAD buffer

Definition at line 899 of file structs.h.

3.26.2.3 dollarname

UBYTE* DoLoOp::dollarname

For loop over terms in expression. Allocated with Malloc1()

Definition at line 902 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.27 DuBiOuS Struct Reference

Data Fields

- LONG name
- WORD node
- WORD dummy

3.27.1 Detailed Description

Definition at line 515 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.28 ECand Class Reference

Public Member Functions

- ECand (int dt, int nplist, int *plst)
- void prECand (const char *msg)

Data Fields

- · Bool det
- int nplist
- int plist [GRCC_MAXMPARTICLES2]

3.28.1 Detailed Description

Definition at line 1062 of file grcc.h.

The documentation for this class was generated from the following file:

grcc.h

3.29 EEdge Class Reference

Public Member Functions

- **EEdge** (EGraph *egrph, int nedges, int nloops)

- WORD * POfill
- WORD * POfull
- char * name
- · ULONG numblocks
- ULONG inbuffer
- LONG POsize
- int handle
- · int active

3.38.1 Detailed Description

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

Definition at line 682 of file structs.h.

3.38.2 Field Documentation

3.38.2.1 handle

int FiLe::handle

Our own handle. Equal -1 if no file exists.

Definition at line 710 of file structs.h.

The documentation for this struct was generated from the following file:

3.39.1 Detailed Description

Definition at line 151 of file structs.h.

The documentation for this struct was generated from the following file:

structs.h

3.40 FiLeInDeX Struct Reference

#include <structs.h>

Data Fields

- POSITION next
- POSITION number
- INDEXENTRY expression [INFILEINDEX]
- SBYTE empty [EMPTYININDEX]

3.40.1 Detailed Description

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct InDeXeNtRy) up to a maximum of INFILEINDEX.

The variable number has been made of type POSITION to avoid padding problems with some types of computers/ \leftarrow OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

Definition at line 138 of file structs.h.

3.40.2 Field Documentation

3.40.2.1 next

POSITION FiLeInDeX::next

Position of next FILEINDEX if any

Definition at line 139 of file structs.h.

3.40.2.2 number

POSITION FiLeInDeX::number

Number of used entries in this index

Definition at line 140 of file structs.h.

3.40.2.3 expression

INDEXENTRY FileInDeX::expression[INFILEINDEX]

File index entries

Definition at line 141 of file structs.h.

3.40.2.4 empty

SBYTE FiLeInDeX::empty[EMPTYININDEX]

Padding to 512 bytes

Definition at line 142 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.41 FixedGlobals Struct Reference

#include <structs.h>

- WCN Operation [8]
- WCN2 OperaFind [6]
- char * **VarType** [10]
- char * ExprStat [21]
- char * FunNam [2]
- char * **swmes** [3]
- char * fname
- char * fname2
- UBYTE * s_one
- WORD fnamebase
- · WORD fname2base
- WORD fnamesize
- WORD fname2size
- UINT cTable [256]

3.41.1 Detailed Description

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements Operation and OperaFind which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file opera.c Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the cTable which is used intensively in the compiler.

Definition at line 2668 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.42 fixedset Struct Reference

Data Fields

- char * name
- char * description

- WORD commute
- WORD complex
- WORD number
- WORD flags
- WORD spec
- WORD symmetric
- WORD node
- WORD namesize
- WORD dimension
- WORD maxnumargs
- WORD minnumargs

3.45.1 Detailed Description

Contains all information about a function. Also used for tables. It is used in the LIST elements of #AC.

Definition at line 477 of file structs.h.

3.45.2 Field Documentation

3.45.2.1 tabl

TABLES FuNcTiOn::tabl

Used if redefined as table. != 0 if function is a table

Definition at line 478 of file structs.h.

3.45.2.2 symminfo

LONG FuNcTiOn::symminfo

Info regarding symm properties offset in buffer

Definition at line 479 of file structs.h.

3.45.2.3 name

LONG FuNcTiOn::name

Location in namebuffer of NAMETREE

Definition at line 480 of file structs.h.

3.45.2.4 commute

WORD FuNcTiOn::commute

Commutation properties

Definition at line 481 of file structs.h.

3.45.2.5 complex

WORD Function::complex

Properties under complex conjugation

Definition at line 482 of file structs.h.

3.45.2.6 number

WORD FuNcTiOn::number

Number when stored in file

Definition at line 483 of file structs.h.

3.45.2.7 flags

WORD FuNcTiOn::flags

Used to indicate usage when storing

Definition at line 484 of file structs.h.

3.45.2.8 spec

WORD FuNcTiOn::spec

Regular, Tensor, etc. See FunSpecs.

Definition at line 485 of file structs.h.

3.45.2.9 symmetric

WORD FuNcTiOn::symmetric

0 if symmetric properties

Definition at line 486 of file structs.h.

3.45.2.10 node

WORD FuNcTiOn::node

Location in namenode of NAMETREE

Definition at line 487 of file structs.h.

3.45.2.11 namesize

WORD FuNcTiOn::namesize

Length of the name

Definition at line 488 of file structs.h.

3.55 KEYWORD Struct Reference

#include <structs.h>

Data Fields

- · char * name
- TFUN func
- int type
- int flags

3.55.1 Detailed Description

The KEYWORD struct defines names of commands/statements and the routine to be called when they are encountered by the compiler or preprocessor.

Definition at line 222 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.56 KEYWORDV Struct Reference

#include <structs.h>

Data Fields

- char * name
- int * var
- int type
- int flags

3.56.1 Detailed Description

The KEYWORDV struct defines names of commands/statements and the variable to be affected when they are encountered by the compiler or preprocessor.

Definition at line 234 of file structs.h.

The documentation for this struct was generated from the following file:

· structs.h

3.57 LIST Struct Reference

#include <structs.h>

Data Fields

- void * lijst
- char * message
- int num
- int maxnum
- int size
- int numglobal
- · int numtemp
- · int numclear

3.57.1 Detailed Description

Much information is stored in arrays of which we can double the size if the array proves to be too small. Such arrays are controlled by a variable of type LIST. The routines that expand the lists are in the file tools.c

Definition at line 205 of file structs.h.

3.57 LIST Struct Reference 61

3.57.2 Field Documentation

3.57.2.1 lijst

void* LIST::lijst

[D] Holds space for "maxnum" elements of size "size" each

Definition at line 206 of file structs.h.

3.57.2.2 message

char* LIST::message

Text for Malloc1 when allocating lijst. Set to constant string.

Definition at line 207 of file structs.h.

3.57.2.3 num

int LIST::num

Number of elements in lijst.

Definition at line 208 of file structs.h.

3.57.2.4 maxnum

int LIST::maxnum

Maximum number of elements in lijst.

Definition at line 209 of file structs.h.

3.57.2.5 size

int LIST::size

Size of one element in lijst.

Definition at line 210 of file structs.h.

3.57.2.6 numglobal

```
int LIST::numglobal
```

Marker for position when .global is executed.

Definition at line 211 of file structs.h.

3.57.2.7 numtemp

```
int LIST::numtemp
```

At the moment only needed for sets and setstore.

Definition at line 212 of file structs.h.

3.57.2.8 numclear

```
int LIST::numclear
```

Only for the clear instruction.

Definition at line 213 of file structs.h.

3.75.1 Detailed Description

The N_const struct is part of the global data and resides either in the ALLGLOBALS struct A, or the ALLPRIVATES struct B (TFORM) under the name N We see it used with the macro AN as in AN.RepFunNum It has variables that are private to each thread and are used as temporary storage during the expansion of the terms tree.

Definition at line 2270 of file structs.h.

3.75.2 Field Documentation

3.75.2.1 SignCheck

WORD N_const::SignCheck

Used in pattern matching of antisymmetric functions

Definition at line 2394 of file structs.h.

3.75.2.2 IndDum

WORD N_const::IndDum

Used in pattern matching of antisymmetric functions

Definition at line 2395 of file structs.h.

The documentation for this struct was generated from the following file:

The documentation for this struct was generated from the following file:

· minos.h

3.77 NaMeNode Struct Reference

#include <structs.h>

Data Fields

- LONG name
- WORD parent
- WORD left
- WORD right
- WORD balance
- WORD type
- WORD number

3.77.1 Detailed Description

The names of variables are kept in an array. Elements of type NAMENODE define a tree (that is kept balanced) that make it easy and fast to look for variables. See also NAMETREE.

Definition at line 247 of file structs.h.

3.77.2 Field Documentation

3.77.2.1 name

LONG NaMeNode::name

Offset into NAMETREE::namebuffer.

Definition at line 248 of file structs.h.

3.77.2.2 parent

WORD NaMeNode::parent

=-1 if no parent.

Definition at line 249 of file structs.h.

3.77.2.3 left

WORD NaMeNode::left

=-1 if no child.

Definition at line 250 of file structs.h.

3.77.2.4 right

WORD NaMeNode::right

=-1 if no child.

Definition at line 251 of file structs.h.

3.77.2.5 balance

WORD NaMeNode::balance

Used for the balancing of the tree.

Definition at line 252 of file structs.h.

3.77.2.6 type

WORD NaMeNode::type

Type associated with the name. See compiler types.

Definition at line 253 of file structs.h.

3.77.2.7 number

WORD NaMeNode::number

Number of variable in LIST's like for example C_const::SymbolList.

Definition at line 254 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.78 NaMeSpAcE Struct Reference

Data Fields

- struct NaMeSpAcE * previous
- struct NaMeSpAcE * next
- NAMETREE * usenames
- UBYTE * name

3.78.1 Detailed Description

Definition at line 658 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

3.79 NaMeTree Struct Reference

#include <structs.h>

Data Fields

- NAMENODE * namenode
- UBYTE * namebuffer
- LONG nodesize
- LONG nodefill
- LONG namesize
- LONG namefill
- · LONG oldnamefill
- LONG oldnodefill
- LONG globalnamefill
- LONG globalnodefill
- LONG clearnamefillLONG clearnodefill
- WORD headnode

3.79.1 Detailed Description

A struct of type NAMETREE controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

Definition at line 265 of file structs.h.

3.79.2 Field Documentation

3.79.2.1 namenode

NAMENODE* NaMeTree::namenode

[D] Vector of NAMENODE's. Number of elements is nodesize. =0 if no memory has been allocated.

Definition at line 266 of file structs.h.

3.79.2.2 namebuffer

UBYTE* NaMeTree::namebuffer

[D] Buffer that holds all the name strings refered to by the NAMENODE's. Allocation size is namesize. =0 if no memory has been allocated.

Definition at line 268 of file structs.h.

3.79.2.3 nodesize

LONG NaMeTree::nodesize

Maximum number of elements in namenode.

Definition at line 271 of file structs.h.

3.79.2.4 nodefill

LONG NaMeTree::nodefill

Number of currently used nodes in namenode.

Definition at line 272 of file structs.h.

3.79.2.5 namesize

LONG NaMeTree::namesize

Allocation size of namebuffer in bytes.

Definition at line 273 of file structs.h.

3.79.2.6 namefill

LONG NaMeTree::namefill

Number of bytes occupied.

Definition at line 274 of file structs.h.

3.79.2.7 oldnamefill

LONG NaMeTree::oldnamefill

UNUSED

Definition at line 275 of file structs.h.

3.79.2.8 oldnodefill

LONG NaMeTree::oldnodefill

UNUSED

Definition at line 276 of file structs.h.

3.79.2.9 globalnamefill

LONG NaMeTree::globalnamefill

Set by .global statement to the value of namefill. When a .store command is processed, this value will be used to reset namefill.

Definition at line 277 of file structs.h.

3.79.2.10 globalnodefill

LONG NaMeTree::globalnodefill

Same usage as globalnamefill, but for nodefill.

Definition at line 279 of file structs.h.

3.79.2.11 clearnamefill

LONG NaMeTree::clearnamefill

Marks the reset point used by the .clear statement.

Definition at line 280 of file structs.h.

3.79.2.12 clearnodefill

LONG NaMeTree::clearnodefill

Marks the reset point used by the .clear statement.

Definition at line 281 of file structs.h.

3.79.2.13 headnode

WORD NaMeTree::headnode

Offset in namenode of head node. =-1 if tree is empty.

Definition at line 282 of file structs.h.

The documentation for this struct was generated from the following file:

• structs.h

Public Member Functions

• bool operator< (const optimization &a) const

- · int type
- int arg1
- int arg2
- · int improve
- vector< WORD > coeff
- vector< int > eqnidxs

3.91.1 Detailed Description

class Optimization

3.91.2 Description

This object represents an optimization. Its type is a number in the range 0 to 5. Depending on this type, the variables arg1, arg2 and coeff indicate:

type==0 : optimization of the form $x[arg1] ^ arg2$ (coeff=empty) type==1 : optimization of the form x[arg1] * x[arg2] (coeff=empty) type==2 : optimization of the form x[arg1] * coeff (arg2=0) type==3 : optimization of the form x[arg1] + coeff (arg2=0) type==5 : optimization of the form x[arg1] + x[arg2] (coeff=empty) type==5 : optimization of the form x[arg1] - x[arg2] (coeff=empty)

Here, "x[arg]" represents a symbol (if positive) or an extrasymbol (if negative). The represented symbol's id is ABS(x[arg])-1.

"eqns" is a list of equation, where this optimization can be performed.

"improve" is the total improvement of this optimization.

3.107.1 Detailed Description

Definition at line 49 of file poly.h.

3.107.2 Member Function Documentation

3.107.2.1 is_dense_univariate()

```
int poly::is_dense_univariate ( ) const
```

Dense univariate detection

3.107.3 Description

This method returns whether the polynomial is dense and univariate. The possible return values are:

-2 is not dense univariate -1 is no variables n>=0 is univariate in n

3.107.4 Notes

A univariate polynomial is considered dense iff more than half of the coefficients a_0...a_deg are non-zero.

Definition at line 2278 of file poly.cc.

Referenced by mul().

3.107.4.1 mul()

Polynomial multiplication

3.107.5 Description

This routine determines which multiplication routine to use for multiplying two polynomials. The logic is as follows:

- If a or b consists of only one term, call mul_one_term;
- · Otherwise, if both are univariate and dense, call mul univar;
- · Otherwise, call mul heap.

Definition at line 1191 of file poly.cc.

References is_dense_univariate(), and mul_heap().

3.107.5.1 divmod()

Polynomial division

3.107.6 Description

This routine determines which division routine to use for dividing two polynomials. The logic is as follows:

- If b consists of only one term, call divmod_one_term;
- Otherwise, if both are univariate and dense, call divmod_univar;
- Otherwise, call divmod_heap.

Definition at line 1852 of file poly.cc.

3.107.6.1 mul_heap()

Multiplication of polynomials with a heap

3.107.7 Description

Multiplies two multivariate polynomials. The next element of the product is efficiently determined by using a heap. If the product of the maximum power in all variables is small, a hash table is used to add equal terms for extra speed.

A heap element h is formatted as follows:

```
• h[0] = index in a
```

- h[1] = index in b
- h[2] = hash code (-1 if no hash is used)
- h[3] = length of coefficient with sign
- h[4...4+AN.poly_num_vars-1] = powers
- h[4+AN.poly_num_vars...4+h[3]-1] = coefficient

Definition at line 957 of file poly.cc.

References RaisPowCached().

Referenced by mul().

3.107.7.1 divmod_univar()

Division of dense univariate polynomials.

3.107.8 Description

Divides two dense univariate polynomials. For each power, the method collects all terms that result in that power.

Relevant formula [Q=A/B, P=SUM(p_i* x^{i}), n=deg(A), m=deg(B)]: q_k = [a_{m+k} - SUM(i=k+1...n-m, b_{m+k-i}*q_i)] / b_m

Definition at line 1372 of file poly.cc.

References RaisPowCached().

3.107.8.1 divmod_heap()

Division of polynomials with a heap

3.107.9 Description

Divides two multivariate polynomials. The next element of the quotient/remainder is efficiently determined by using a heap. If the product of the maximum power in all variables is small, a hash table is used to add equal terms for extra speed.

If the input flag check_div is set then if the result of any coefficient division results in a non-zero remainder (indicating that division has failed over the integers) the output flag div_fail will be set and the division will be terminated early (q, r will be incorrect). If check_div is not set then non-zero remainders from coefficient division will be written into r.

A heap element h is formatted as follows:

```
• h[0] = index in a
```

- h[1] = index in b
- h[2] = -1 (no hash is used)
- h[3] = length of coefficient with sign
- h[4...4+AN.poly_num_vars-1] = powers
- h[4+AN.poly_num_vars...4+h[3]-1] = coefficient

Note: the hashing trick as in multiplication cannot be used easily, since there is no tight upperbound on the exponents in the answer.

For details, see M. Monagan, "Polynomial Division using Dynamic Array, Heaps, and Packed Exponent Vectors"

3.118 SETUPPARAMETERS Struct Reference

#include <structs.h>

Data Fields

- UBYTE * parameter
- · int type
- · int flags
- · LONG value

3.118.1 Detailed Description

Each setup parameter has one element of the struct SETUPPARAMETERS assigned to it. By binary search in the array of them we can then locate the proper element by name. We have to assume that two ints make a long and either one or two longs make a pointer. The long before the ints and padding gives a problem in the initialization.

Definition at line 1038 of file structs.h.

3.121.1 Detailed Description

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

- UBYTE sFun
- UBYTE maxpower [16]
- UBYTE wildoffset [16]
- UBYTE revision
- UBYTE reserved [512-8-4-16-4-16-1]

3.125.1 Detailed Description

Defines the structure of the file header for store-files and save-files.

The first 8 bytes serve as a unique mark to identity save-files that contain such a header. Older versions of FORM don't have this header and will write the POSITION of the next file index (struct FiLeInDeX) here, which is always different from this pattern.

It is always 512 bytes long.

Definition at line 75 of file structs.h.

3.125.2 Field Documentation

3.125.2.1 headermark

UBYTE STOREHEADER::headermark[8]

Pattern for header identification. Old versions of FORM have a maximum sizeof(POSITION) of 8

Definition at line 76 of file structs.h.

3.125.2.2 lenWORD

UBYTE STOREHEADER::lenWORD

Number of bytes for WORD

Definition at line 78 of file structs.h.

3.125.2.3 lenLONG

UBYTE STOREHEADER::lenLONG

Number of bytes for LONG

Definition at line 79 of file structs.h.

3.125.2.4 lenPOS

UBYTE STOREHEADER::lenPOS

Number of bytes for POSITION

Definition at line 80 of file structs.h.

3.125.2.5 **lenPOINTER**

UBYTE STOREHEADER::lenPOINTER

Number of bytes for void *

Definition at line 81 of file structs.h.

3.125.2.6 endianness

UBYTE STOREHEADER::endianness[16]

Used to determine endianness, sizeof(int) should be <= 16

Definition at line 82 of file structs.h.

3.125.2.7 sSym

UBYTE STOREHEADER::sSym

sizeof(struct SyMbOI)

Definition at line 83 of file structs.h.

3.125.2.8 sInd

3.126.1 Detailed Description

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i'b

Definition at line 736 of file structs.h.

- WORD bufnum
- WORD bufferssize
- WORD buffersfill
- WORD tablenum
- WORD mode
- WORD numdummies

3.140.1 Detailed Description

buffers, mm, flags, and prototype are always dynamically allocated, tablepointers only if needed (=0 if unallocated), boomlijst and argtail only for sparse tables.

Allocation is done for both the normal and the stub instance (spare), except for prototype and argtail which share memory.

Definition at line 350 of file structs.h.

3.140.2 Field Documentation

3.140.2.1 tablepointers

```
WORD* TaBlEs::tablepointers
```

[D] Start in tablepointers table.

Definition at line 351 of file structs.h.

3.140.2.2 prototype

```
WORD* TaBlEs::prototype
```

[D] The wildcard prototyping for arguments

Definition at line 356 of file structs.h.

3.140.2.3 pattern

```
WORD* TaBlEs::pattern
```

The pattern with which to match the arguments

Definition at line 357 of file structs.h.

3.140.2.4 mm

```
MINMAX* TaBlEs::mm
```

[D] Array bounds, dimension by dimension. # elements = numind.

Definition at line 359 of file structs.h.

3.140.2.5 flags

```
WORD* TaBlEs::flags
```

[D] Is element in use ? etc. # elements = numind.

Definition at line 360 of file structs.h.

3.140.2.6 boomlijst

```
COMPTREE* TaBlEs::boomlijst
```

[D] Tree for searching in sparse tables

Definition at line 361 of file structs.h.

3.140.2.7 argtail

```
UBYTE* TaBlEs::argtail
```

[D] The arguments in characters. Starts for tablebase with parenthesis to indicate tail

Definition at line 362 of file structs.h.

3.140.2.8 spare

```
struct TaBlEs* TaBlEs::spare
```

[D] For tablebase. Alternatingly stubs and real

Definition at line 364 of file structs.h.

3.140.2.9 buffers

```
WORD* TaBlEs::buffers
```

[D] When we use more than one compiler buffer.

Definition at line 365 of file structs.h.

3.140.2.10 totind

LONG TaBlEs::totind

Total number requested

Definition at line 366 of file structs.h.

3.140.2.11 reserved

LONG TaBlEs::reserved

Total reservation in tablepointers for sparse

Definition at line 367 of file structs.h.

3.140.2.12 defined

LONG TaBlEs::defined

Number of table elements that are defined

Definition at line 368 of file structs.h.

3.140.2.13 mdefined

LONG TaBlEs::mdefined

Same as defined but after .global

Definition at line 369 of file structs.h.

3.140.2.14 prototypeSize

int TaBlEs::prototypeSize

Size of allocated memory for prototype in bytes.

Definition at line 370 of file structs.h.

3.140.2.15 numind

int TaBlEs::numind

Number of array indices

Definition at line 371 of file structs.h.

3.140.2.16 bounds

int TaBlEs::bounds

Array bounds check on/off.

Definition at line 372 of file structs.h.

3.140.2.17 strict

int TaBlEs::strict

>0: all must be defined. <0: undefined not substitute

Definition at line 373 of file structs.h.

3.140.2.18 sparse

int TaBlEs::sparse

0 --> sparse table

Definition at line 374 of file structs.h.

3.140.2.19 numtree

int TaBlEs::numtree

For the tree for sparse tables

Definition at line 375 of file structs.h.

3.140.2.20 rootnum

int TaBlEs::rootnum

For the tree for sparse tables

Definition at line 376 of file structs.h.

3.140.2.21 MaxTreeSize

int TaBlEs::MaxTreeSize

For the tree for sparse tables

Definition at line 377 of file structs.h.

3.140.2.22 bufnum

WORD TaBlEs::bufnum

Each table potentially its own buffer

Definition at line 378 of file structs.h.

3.140.2.23 bufferssize

WORD TaBlEs::bufferssize

When we use more than one compiler buffer

Definition at line 379 of file structs.h.

3.140.2.24 buffersfill

WORD TaBlEs::buffersfill

When we use more than one compiler buffer

Definition at line 380 of file structs.h.

3.140.2.25 tablenum

WORD TaBlEs::tablenum

For testing of tableuse

Definition at line 381 of file structs.h.

3.140.2.26 mode

WORD TaBlEs::mode

0: normal, 1: stub

Definition at line 382 of file structs.h.

3.143.1 Detailed Description

The struct TRACEN keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue.

Definition at line 822 of file structs.h.

The documentation for this struct was generated from the following file:

3.144.1 Detailed Description

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

Definition at line 789 of file structs.h.

3.145 tree Struct Reference

#include <structs.h>

Data Fields

- · int parent
- int left
- int right
- int value
- int blnce
- · int usage

3.145.1 Detailed Description

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxxx occurrences of objects like f(x+1,x+1) in which each x+1 becomes a subexpression. The struct that controls this tree is COMPTREE.

4.1.1 Detailed Description

Contains the routines that deal with the execution phase of the argument and related statements (like term)

4.1.2 Macro Definition Documentation

4.1.2.1 NEWORDER

```
#define NEWORDER
```

Factorizes an argument in general notation (meaning that the first word of the argument is a positive size indicator) Input (argin): pointer to the complete argument Output (argout): Pointer to where the output should be written. This is in the WorkSpace Return value should be negative if anything goes wrong.

The notation of the output should be a string of arguments terminated by the number zero.

Originally we sorted in a way that the constants came last. This gave conflicts with the dollar and expression factorizations (in the expressions we wanted the zero first and then followed by the constants).

Definition at line 2045 of file argument.c.

4.1.3 Function Documentation

4.1.3.1 FindArg()

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2495 of file argument.c.

4.1.3.2 InsertArg()

```
WORD InsertArg (

PHEAD WORD * argin,

WORD * argout,

int par )
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2519 of file argument.c.

4.1.3.3 CleanupArgCache()

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2554 of file argument.c.

4.1.3.4 TakeArgContent()

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2748 of file argument.c.

4.1.3.5 MakeInteger()

```
WORD* MakeInteger (

PHEAD WORD * argin,

WORD * argout,

WORD * argfree )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3294 of file argument.c.

4.1.3.6 MakeMod()

```
WORD* MakeMod (

PHEAD WORD * argin,

WORD * argout,

WORD * argfree )
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3465 of file argument.c.

4.1.3.7 SortWeights()

Sorts an array of LONGS in the same way SplitMerge (in sort.c) works We use gradual division in two.

Definition at line 3510 of file argument.c.

4.3.1 Detailed Description

Contains all functions that deal with the recovery mechanism controlled and activated by the On Checkpoint switch.

The main function are DoCheckpoint, DoRecovery, and DoSnapshot. If the checkpoints are activated DoCheckpoint is called every time a module is finished executing. If the conditions for the creation of a recovery snapshot are met DoCheckpoint calls DoSnapshot. DoRecovery is called once when FORM starts up with the command line argument -R. Most of the other code contains debugging facilities that are only compiled if the macro PRINTDEBUG is defined.

The recovery mechanism is atomic, i.e. only if everything went well, the final recovery file is created (and the older one overwritten) in a single step (copying). If some errors occur, a warning is issued and the program continues without having created a new recovery file. The only situation in which the creation of the recovery data leads to a termination of the running program is if not enough disk or memory space is left.

For ParFORM each slave creates its own recovery file, sends it to the master and then it deletes the recovery file. The master stores all the recovery files and on recovery it feeds these files to the slaves. It is nearly impossible to recover after some MPI fault so ParFORM terminates on any recovery failure.

DoRecovery and DoSnapshot do the loading and saving of the recovery data, respectively. Every change in one functions needs to be accompanied by the appropriate change in the other function. The structure of both functions is quite similar. They handle the relevant global structs one after the other and then care about the copying of the hide and scratch files.

The names of the recovery, scratch and hide files are hard-coded in the variables in fold "filenames and system commands".

If the global structs AM,AP,AC,AR are changed, DoRecovery and DoSnapshot usually also have to be changed. Some structs are read/written as a whole (AP,AC), some are read/written only partly as a selection of their individual elements (AM,AR). If AM or AR have been changed by adding or removing an element that is important for the runtime status, then the reading/writing statements have to be added to or removed from DoRecovery and Do \leftarrow Snapshot. If AP or AC are changed, then for non-pointer variables (in the case of a struct it also means that none of its elements is a pointer) nothing has to be changed in the functions here. If pointers are involved, extra code has to be added (or removed). See the comments of DoRecovery and DoSnapshot.

4.3.3 Function Documentation

4.3.3.1 CheckRecoveryFile()

Checks whether a snapshot/recovery file exists. Returns 1 if it exists, 0 otherwise.

Definition at line 278 of file checkpoint.c.

4.3.3.2 DeleteRecoveryFile()

Deletes the recovery files. It is called by CleanUp() in the case of a successful completion.

Definition at line 333 of file checkpoint.c.

4.3.3.3 RecoveryFilename()

Returns pointer to recovery filename.

Definition at line 364 of file checkpoint.c.

4.3.3.4 InitRecovery()

Sets up the strings for the filenames of the recovery files. This functions should only be called once to avoid memory leaks and after AM.TempDir has been initialized.

Definition at line 399 of file checkpoint.c.

4.3.3.5 DoRecovery()

```
int DoRecovery (
    int * moduletype )
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Definition at line 1401 of file checkpoint.c.

4.3.3.6 DoCheckpoint()

```
void DoCheckpoint (
          int moduletype )
```

Checks whether a snapshot should be done. Calls DoSnapshot() to create the snapshot.

Definition at line 3108 of file checkpoint.c.

4.5.1 Detailed Description

Compiler routines for most statements that don't involve algebraic expressions. Exceptions: all routines involving declarations are in the file names.c When making new statements one can add the compiler routines here and have a look whether there is already a routine that is similar. In that case one can make a copy and modify it.

4.6.1 Detailed Description

The heart of the compiler. It contains the tables of statements. It finds the statements in the tables and calls the proper routines. For algebraic expressions it runs the compilation by first calling the tokenizer, splitting things into subexpressions and generating the code. There is a system for recognizing already existing subexpressions. This economizes on the length of the output.

Note: the compiler of FORM doesn't attempt to normalize the input. Hence x+1 and 1+x are different objects during compilation. Similarly (a+b-b) will not be simplified to (a).

4.6.2 Macro Definition Documentation

4.6.2.1 REDUCESUBEXPBUFFERS

```
#define REDUCESUBEXPBUFFERS
```

Value:

```
{ if ( (topsubexpbuffers-subexpbuffers) > 256 ) {\
M_free(subexpbuffers, "subexpbuffers");\
subexpbuffers = (SUBBUF *)Malloc1(256*sizeof(SUBBUF), "subexpbuffers");\
topsubexpbuffers = subexpbuffers+256; } insubexpbuffers = 0; }
```

4.8.1 Detailed Description

Utility routines for the compiler.

4.8.2 Function Documentation

4.8.2.1 inicbufs()

```
int inicbufs ( VOID )
```

Creates a new compiler buffer and returns its ID number.

Returns

The ID number for the new compiler buffer.

Definition at line 47 of file comtool.c.

4.8.2.2 finishcbuf()

Frees a compiler buffer.

Parameters

```
num The ID number for the buffer to be freed.
```

Definition at line 89 of file comtool.c.

4.8.2.3 clearcbuf()

Clears contents in a compiler buffer.

Parameters

num The ID number for the buffer to be cleared.

Definition at line 116 of file comtool.c.

4.8.2.4 DoubleCbuffer()

```
WORD* DoubleCbuffer (  \mbox{int } num, \\ \mbox{WORD} * \mbox{w,} \\ \mbox{int } par \mbox{)}
```

Doubles a compiler buffer.

Parameters

num	D number for the buffer to be doubled.	
W	The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer,w)	
	will be kept.	

Definition at line 143 of file comtool.c.

4.8.2.5 AddLHS()

```
WORD* AddLHS ( int num )
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

num	The ID number for the buffer to get another LHS.
Hulli	The 1D hamber for the buner to get another End.

Definition at line 188 of file comtool.c.

4.8.2.6 AddRHS()

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
tvpe	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

4.8.2.7 AddNtoL()

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

4.8.2.8 AddNtoC()

```
int AddNtoC (
        int bufnum,
        int n,
        WORD * array,
        int par )
```

Adds the given data to the last LHS/RHS in a compiler buffer.

Parameters

bufnum	The ID number for the buffer where the data will be added.
n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 317 of file comtool.c.

4.8.2.9 IniFbuffer()

Initialize a factorization cache buffer. We set the size of the rhs and boomlijst buffers immediately to their final values.

Definition at line 614 of file comtool.c.

4.9 comtool.h File Reference

```
#include "form3.h"
```

4.9.1 Detailed Description

Utility routines for the compiler.

4.10 declare.h File Reference

4.10.1 Detailed Description

Contains macros and function declarations.

4.10.2 Macro Definition Documentation

4.10.2.1 TOKENTOLINE

Definition at line 53 of file declare.h.

4.10.2.2 ParseSign

```
#define ParseSign(

sgn,

s)
```

Value:

```
{ (sgn) = 0; while (*(s) =='-'||*(s) =='+') {\ if (*(s) ++ == '-') sgn ^= 1; }}
```

Definition at line 65 of file declare.h.

4.10.2.3 ParseSignedNumber

Definition at line 67 of file declare.h.

4.10.2.4 NeedNumber

Definition at line 77 of file declare.h.

4.10.2.5 SKIPBRA1

Definition at line 87 of file declare.h.

4.10.2.6 SKIPBRA2

Definition at line 89 of file declare.h.

4.10.2.7 SKIPBRA3

Definition at line 92 of file declare.h.

4.10.2.8 SKIPBRA4

```
#define SKIPBRA4( s )
```

Value:

```
{ int lev4=0; s++; while(*s) { if(*s=='(')lev4++; \ else if(*s==')'&&--lev4<0)break; \ else if(*s=='[')SKIPBRA1(s) s++; } }
```

Definition at line 96 of file declare.h.

4.10.2.9 SKIPBRA5

Value:

```
{ int lev5=0; s++; while(*s) { if(*s=='{')lev5++; \ else if(*s=='}'&&--lev5<0)break; \ else if(*s=='(')SKIPBRA4(s) \ else if(*s=='[')SKIPBRA1(s) s++; } }
```

Definition at line 99 of file declare.h.

4.10.2.10 AddToCB

```
#define AddToCB( _{C}, _{WX} )
```

Value:

```
if(c->Pointer>=c->Top) \
DoubleCbuffer(c-cbuf,c->Pointer,21); \
*(c->Pointer)++ = wx;
```

Definition at line 109 of file declare.h.

4.10.2.11 EXCHINOUT

```
#define EXCHINOUT
```

Value:

```
{ FILEHANDLE *ffFi = AR.outfile; \
AR.outfile = AR.infile; AR.infile = ffFi; }
```

Definition at line 113 of file declare.h.

4.10.2.12 BACKINOUT

```
#define BACKINOUT
```

Value:

```
{ FILEHANDLE *ffFi = AR.outfile; POSITION posi; \
AR.outfile = AR.infile; AR.infile = ffFi; \
SetEndScratch(AR.infile,&posi); }
```

Definition at line 115 of file declare.h.

4.10.2.13 CopyArg

Definition at line 119 of file declare.h.

4.10.2.14 COPY1ARG

Value:

```
{ int ica; if ( (ica=*t1) > 0 ) { NCOPY(s1,t1,ica) } \ else if (*t1<=-FUNCTION) {*s1++=*t1++;} else {*s1++=*t1++;} }
```

Definition at line 164 of file declare.h.

4.10.2.15 ZeroFillRange

Fills a buffer by zero in the range [begin,end).

Parameters

W	The buffer.	
begin	The index for the beginning of the range.	
end	The index for the end of the range (exclusive).	

Definition at line 174 of file declare.h.

4.10.2.16 Add4Com

```
#define Add4Com(
     x1,
     x2,
     x3 )
```

Value:

```
{ WORD cod[4]; cod[0] = x1; cod[1] = 4; \ cod[2] = x2; cod[3] = x3; AddNtoL(4,cod); }
```

Definition at line 248 of file declare.h.

4.10.2.17 Add5Com

Value:

```
WORD cod[5]; cod[0] = x1; cod[1] = 5; \
cod[2] = x2; cod[3] = x3; cod[4] = x4; AddNtoL(5,cod); }
```

Definition at line 250 of file declare.h.

4.10.2.18 WantAddPointers

```
\begin{tabular}{ll} \# define & WantAddPointers ( \\ & x \ ) \end{tabular}
```

Value:

```
while((AT.pWorkPointer+(x))>AR.pWorkSize){WORD ***ppp=&AT.pWorkSpace;\
ExpandBuffer((void **)ppp,&AR.pWorkSize,(int)(sizeof(WORD *)));}
```

Definition at line 256 of file declare.h.

4.10.2.19 WantAddLongs

```
#define WantAddLongs( x )
```

Value:

```
while((AT.lWorkPointer+(x))>AR.lWorkSize) {LONG **ppp=&AT.lWorkSpace;\
ExpandBuffer((void **)ppp,&AR.lWorkSize,sizeof(LONG));}
```

Definition at line 258 of file declare.h.

4.10.2.20 WantAddPositions

Value:

```
while((AT.posWorkPointer+(x))>AR.posWorkSize){POSITION **ppp=&AT.posWorkSpace;\
ExpandBuffer((void **)ppp, &AR.posWorkSize, sizeof(POSITION));}
```

Definition at line 260 of file declare.h.

4.10.2.21 MarkPolyRatFunDirty

```
\label{eq:define_mark} \mbox{\tt \#define MarkPolyRatFunDirty(}} $$T$ )
```

Value:

```
{if(*T&&AR.PolyFunType==2){WORD *TP,*TT;TT=T+*T;TT=ABS(TT[-1]);\
TP=T+1;while(TP<TT){if(*TP==AR.PolyFun){TP[2]|=(DIRTYFLAG|MUSTCLEANPRF);}TP+=TP[1];}}}</pre>
```

Definition at line 312 of file declare.h.

4.10.2.22 PUSHPREASSIGNLEVEL

```
#define PUSHPREASSIGNLEVEL
```

Value:

```
AP.PreAssignLevel++; { GETIDENTITY \
if ( AP.PreAssignLevel >= AP.MaxPreAssignLevel ) { int i; \
   LONG *ap = (LONG *) Malloc1(2*AP.MaxPreAssignLevel*sizeof(LONG *), "PreAssignStack"); \
   for ( i = 0; i < AP.MaxPreAssignLevel; i++ ) ap[i] = AP.PreAssignStack[i]; \
   M_free(AP.PreAssignStack, "PreAssignStack"); \
   AP.MaxPreAssignLevel *= 2; AP.PreAssignStack = ap; \
} \
   *AT.WorkPointer++ = AP.PreContinuation; AP.PreContinuation = 0; \
   AP.PreAssignStack[AP.PreAssignLevel] = AC.iPointer - AC.iBuffer; }</pre>
```

Definition at line 319 of file declare.h.

4.10.2.23 POPPREASSIGNLEVEL

```
#define POPPREASSIGNLEVEL
```

Value:

```
if ( AP.PreAssignLevel > 0 ) { GETIDENTITY \
AC.iPointer = AC.iBuffer + AP.PreAssignStack[AP.PreAssignLevel--]; \
AP.PreContinuation = *--AT.WorkPointer; \
*AC.iPointer = 0; }
```

Definition at line 329 of file declare.h.

4.10.2.24 EXTERNLOCK

```
#define EXTERNLOCK( x )
```

NOTE: We have replaced LOCK(ErrorMessageLock) and UNLOCK(ErrorMessageLock) by MLOCK(Error WessageLock) and MUNLOCK(ErrorMessageLock). They are used for the synchronised output in ParFORM. (TU 28 May 2011)

Definition at line 475 of file declare.h.

4.10.3 Function Documentation

4.10.3.1 StartVariables()

All functions (well, nearly all) are declared here.

Definition at line 871 of file startup.c.

4.10.3.2 PasteTerm()

```
WORD* PasteTerm (

PHEAD WORD number,

WORD * accum,

WORD * position,

WORD times,

WORD divby)
```

Puts the term at position in the accumulator accum at position 'number+1'. if times > 0 the coefficient of this term is multiplied by times/divby.

Parameters

number	The number of term fragments in accum that should be skipped	
accum	The accumulator of term fragments	
position	A position in (typically) a compiler buffer from where a (piece of a) term comes.	
times	Multiply the result by this	
divby	Divide the result by this.	

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors times and divby keep track of the binomial coefficient. Once this is complete, the routine FiniTerm will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line 2978 of file proces.c.

4.10.3.3 AddArgs()

```
VOID AddArgs (

PHEAD WORD * s1,

WORD * s2,

WORD * m )
```

Adds the arguments of two occurrences of the PolyFun.

Parameters

s1	Pointer to the first occurrence.
s2	Pointer to the second occurrence.
m	Pointer to where the answer should be.

Definition at line 2272 of file sort.c.

4.10.3.4 AddCoef()

```
WORD AddCoef (

PHEAD WORD ** ps1,

WORD ** ps2)
```

Adds the coefficients of the terms *ps1 and *ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not succesfull we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in *ps1.

Definition at line 1981 of file sort.c.

4.10.3.5 AddPoly()

```
WORD AddPoly (  \mbox{PHEAD WORD ** } ps1, \\ \mbox{WORD ** } ps2 \mbox{ ) }
```

Routine should be called when S->PolyWise != 0. It points then to the position of AR.PolyFun in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case S->PolyFlag is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

Parameters

ps1	A pointer to the postion of the first term
ps2	A pointer to the postion of the second term

Returns

If zero the terms cancel. Otherwise the new term is in *ps1.

Definition at line 2110 of file sort.c.

4.10.3.6 CompCoef()

```
WORD CompCoef ( WORD * term1, \\ WORD * term2 ) Routine takes al mod m1 and a2 mod m2 and returns a mod m1*m2 with a mod m1 = a1 and a mod m2 = a2
```

Chinese remainder: a%(m1*m2) = q1*m1+a1 a%(m1*m2) = q2*m2+a2 Compute n1 such that (n1*m1)m2 is one Compute n2 such that (n2*m2)m1 is one Then (a1*n2*m2+a2*n1*m1)%(m1*m2) is a%(m1*m2)

Definition at line 3047 of file reken.c.

4.10.3.7 Compare1()

```
WORD Compare1 (
          PHEAD WORD * term1,
          WORD * term2,
          WORD level )
```

Compares two terms. The answer is: 0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

Parameters

term1	First input term	
term2	Second input term	
level	evel The sorting level (may influence on the result)	

Returns

0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first.

When there are floating point numbers active (float_ = FLOATFUN) the presence of one or more float_ functions is returned in AT.SortFloatMode: 0: no float 1: float in term1 only 2: float in term2 only 3: float in both terms

Definition at line 2565 of file sort.c.

4.10.3.8 Deferred()

```
WORD Deferred (

PHEAD WORD * term,

WORD level )
```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

term	The term that must be multiplied by the contents of the current bracket
level	The compiler level. This is needed because after multiplying term by term we call Generator again.

Definition at line 4810 of file proces.c.

4.10.3.9 DoOnePow()

```
WORD DoOnePow (

PHEAD WORD * term,

WORD power,

WORD nexp,

WORD * accum,

WORD * aa,

WORD level,

WORD * freeze )
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commutating properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

term	is the term we are adding to.	
power	is the power of the expression that we need.	
nexp	is the number of the expression.	
accum	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm	
aa	points to the start of the entire accumulator. In *aa we store the number of term fragments that are in the accumulator.	
level	is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term	
freeze	is the pointer to the bracket information that should be matched.	

Definition at line 4589 of file proces.c.

4.10.3.10 EndSort()

```
LONG EndSort (  \mbox{PHEAD WORD} \ * \ buffer,   \mbox{int } par \ )
```

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel > 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 Output to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for \$-variable. We return the address of the buffer that contains the output in buffer (treated like WORD **). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.SO.

Parameters

buffer	buffer for output when needed
par	See above

Returns

If negative: error. If positive: number of words in output.

Definition at line 682 of file sort.c.

4.10.3.11 FiniTerm()

```
WORD FiniTerm (

PHEAD WORD * term,

WORD * accum,

WORD * termout,

WORD number,

WORD tepos)
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

term	the input term with the (sub)expression subterm
accum	the accumulator with the term fragments
termout	the location where the output should be written
number	the number of term fragments in the accumulator
tepos	the position of the subterm in term to be replaced

Definition at line 3043 of file proces.c.

4.10.3.12 FlushOut()

Completes output to an output file and writes the trailing zero.

Parameters

position	The position in the file after writing	
fi	The file (or its cache)	
compr Indicates whether there should be compression with gz		

Returns

Regular conventions (OK -> 0).

Definition at line 1767 of file sort.c.

4.10.3.13 GarbHand()

```
VOID GarbHand ( VOID )
```

Garbage collection that takes place when the small extension is full and we need to place more terms there. When this is the case there are many holes in the small buffer and the whole can be compactified. The major complication is the buffer for SplitMerge. There are to options for temporary memory: 1: find some buffer that has enough space (maybe in the large buffer). 2: allocate a buffer. Give it back afterwards of course. If the small extension is properly dimensioned this routine should be called very rarely. Most of the time it will be called when the polyfun or polyratfun is active.

Definition at line 3513 of file sort.c.

4.10.3.14 Generator()

```
WORD Generator (

PHEAD WORD * term,

WORD level )
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

te	erm	the input term. may be overwritten
le	evel	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

Definition at line 3242 of file proces.c.

4.10.3.15 InFunction()

```
WORD InFunction (

PHEAD WORD * term,

WORD * termout )
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

term	The input term
termout	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

Special attention should be given to nested functions!

Definition at line 2174 of file proces.c.

4.10.3.16 InsertTerm()

```
WORD InsertTerm (

PHEAD WORD * term,

WORD replac,

WORD extractbuff,

WORD * position,

WORD * termout,

WORD tepos)
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

term	the input term	
replac	number of the subexpression pointer to replace	
extractbuff	number of the compiler buffer replac refers to	
position	position from where to take the term in the compiler buffer	
termout	the output term	
tepos	offset in term where the subexpression is.	

Returns

Normal conventions (OK = 0).

Definition at line 2720 of file proces.c.

4.10.3.17 MergePatches()

```
WORD MergePatches ( \label{eq:word_par} \text{WORD } par \ )
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

Parameters

par

If par == 0 the sort is for file -> outputfile. If par == 1 the sort is for large buffer -> sortfile. If par == 2 the sort is for large buffer -> outputfile.

Definition at line 3628 of file sort.c.

4.10.3.18 NewSort()

```
WORD NewSort ( PHEADO )
```

Starts a new sort. At the lowest level this is a 'main sort' with the struct according to the parameters in S0. At higher levels this is a sort for functions, subroutines or dollars. We prepare the arrays and structs.

Returns

Regular convention (OK -> 0)

Definition at line 592 of file sort.c.

4.10.3.19 PasteFile()

```
LONG PasteFile (

PHEAD WORD number,

WORD * accum,

POSITION * position,

WORD ** accfill,

RENUMBER renumber,

WORD * freeze,

WORD nexpr)
```

Gets a term from stored expression expr and puts it in the accumulator at position number. It returns the length of the term that came from file.

Parameters

number	number of partial terms to skip in accum
accum	the accumulator
position	file position from where to get the stored term
accfill	returns tail position in accum
renumber	the renumber struct for the variables in the stored expression
freeze	information about if we need only the contents of a bracket
nexpr	the number of the stored expression

Returns

Normal conventions (OK = 0).

Definition at line 2856 of file proces.c.

4.10.3.20 PolyFunMul()

```
WORD PolyFunMul ( {\tt PHEAD\ WORD\ *\ term\ )}
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file polywrap.cc The new result is written over the old result.

Parameters

term	It contains the input term and later the output.
------	--

Returns

Normal conventions (OK = 0).

Definition at line 5326 of file proces.c.

4.10.3.21 PrepPoly()

```
WORD PrepPoly (

PHEAD WORD * term,

WORD par )
```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter par tells whether we are at groundlevel or inside a function or dollar variable.

Definition at line 4938 of file proces.c.

4.10.3.22 Processor()

```
WORD Processor ( VOID )
```

This is the central processor. It accepts a stream of Expressions which is accessed by calls to GetTerm. The expressions reside either in AR.infile or AR.hidefile The definitions of an expression are seen as an id-statement, so the primary Expressions should be written to the system of scratch files as single terms with an expression pointer. Each expression is terminated with a zero and the whole is terminated by two zeroes.

The routine DoExecute should determine whether results are to be printed, should revert the scratch I/O directions etc. In principle it is DoExecute that calls Processor.

Returns

if everything OK: 0. Otherwise error. The preprocessor may continue with compilation though. Really fatal errors should return on the spot by calling Terminate.

Definition at line 64 of file proces.c.

4.10.3.23 PutIn()

```
LONG PutIn (

FILEHANDLE * file,

POSITION * position,

WORD * buffer,

WORD ** take,

int npat )
```

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

Parameters

file	The file system from which to read	
position	The position from which to read	
buffer	The buffer into which to read	
take	The unused tail should be moved before the buffer	
npat	The number of the patch. Is needed if the information was compressed with gzip, because each	
	patch has its own independent gzip encoding. Generated by Doxygen	

Definition at line 1259 of file sort.c.

4.10.3.24 PutOut()

```
WORD PutOut (

PHEAD WORD * term,

POSITION * position,

FILEHANDLE * fi,

WORD ncomp )
```

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain: 1: a list with brackets array with the brackets 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

Parameters

term	The term to be written	
position	The position in the file. Afterwards it is updated	
fi	The file (or its cache) to which should be written	
ncomp	Information about what type of compression should be used	

Definition at line 1405 of file sort.c.

4.10.3.25 RaisPowCached()

```
VOID RaisPowCached (

PHEAD WORD x,

WORD n,

UWORD ** c,

WORD * nc )
```

Computes power x^n and caches the value

4.10.4 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.10.5 Notes

• Caching is done in AT.small_power[]. This array is extended if necessary.

Definition at line 1296 of file reken.c.

Referenced by poly::divmod_univar(), and poly::mul_heap().

4.10.5.1 NormalModulus()

```
int NormalModulus ( {\tt UWORD} \, * \, a \text{,} \\ {\tt WORD} \, * \, na \, )
```

Brings a modular representation in the range -p/2 to +p/2 The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1403 of file reken.c.

4.10.5.2 MakeInverses()

Makes a table of inverses in modular calculus The modulus is in AC.cmod and AC.ncmod One should notice that the table of inverses can only be made if the modulus fits inside a single FORM word. Otherwise the table lookup becomes too difficult and the table too long.

Definition at line 1440 of file reken.c.

4.10.5.3 GetModInverses()

```
int GetModInverses (
     WORD m1,
     WORD m2,
     WORD * im1,
     WORD * im2 )
```

Input m1 and m2, which are relative prime. determines a*m1+b*m2 = 1 (and 1 is the gcd of m1 and m2) then $a*m1 = 1 \mod m2$ and hence im1 = a. and $b*m2 = 1 \mod m1$ and hence im2 = b. Set m1 = 0*m1+1*m2 = a1*m1+b1*m2 m2 = 1*m1+0*m2 = a2*m1+b2*m2 If everything is OK, the return value is zero

Definition at line 1476 of file reken.c.

4.10.5.4 SetFileIndex()

```
WORD SetFileIndex ( VOID )
```

Reads the next file index and puts it into AR.StoreData.Index. TODO

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 2306 of file store.c.

4.10.5.5 Sflush()

```
WORD Sflush ( FILEHANDLE * fi )
```

Puts the contents of a buffer to output Only to be used when there is a single patch in the large buffer.

Parameters

fi The filesystem (or its cache) to which the patch should be written

Definition at line 1319 of file sort.c.

4.10.5.6 SortWild()

Sorts the wildcard entries in the parameter w. Double entries are removed. Full space taken is nw words. Routine serves for the reading of wildcards in the compiler. The entries come in the format: (type,4,number,0) in which the zero is reserved for the future replacement of 'number'.

Parameters

W	buffer with wildcard entries.
nw	number of wildcard entries.

Returns

Normal conventions (OK -> 0)

Definition at line 4613 of file sort.c.

4.10.5.7 SplitMerge()

```
LONG SplitMerge (
          PHEAD WORD ** Pointer,
          LONG number )
```

Algorithm by J.A.M. Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

Parameters

Pointer	The array of pointers to the terms to be sorted.
number	The number of pointers in Pointer.

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

Definition at line 3291 of file sort.c.

4.10.5.8 StoreTerm()

```
\label{eq:word_store} \mbox{WORD StoreTerm (} \\ \mbox{PHEAD WORD * } term \mbox{ )}
```

The central routine to accept terms, store them and keep things at least partially sorted. A call to EndSort will then complete storing and sorting.

Parameters

erm The term to be stored

Returns

Regular return conventions (OK -> 0)

Definition at line 4394 of file sort.c.

4.10.5.9 TermRenumber()

```
WORD TermRenumber (

WORD * term,

RENUMBER renumber,

WORD nexpr )
```

!! WORD *memterm=term; static LONG ctrap=0; !!!

!! ctrap++; !!!

Definition at line 2413 of file store.c.

4.10.5.10 TestMatch()

```
WORD TestMatch (

PHEAD WORD * term,

WORD * level )
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in *AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

Definition at line 97 of file pattern.c.

4.10.5.11 TimeCPU()

```
LONG TimeCPU ( WORD par )
```

Returns the CPU time.

Parameters

```
par If zero, the CPU time will be reset to 0.
```

Returns

The CPU time in milliseconds.

Definition at line 3550 of file tools.c.

4.10.5.12 TimeWallClock()

```
LONG TimeWallClock (
WORD par )
```

Returns the wall-clock time.

Parameters

clock time will be reset to 0.	par If zero, the v
--------------------------------	--------------------

Returns

The wall-clock time in centiseconds.

Definition at line 3476 of file tools.c.

Referenced by DoCheckpoint().

4.10.5.13 WriteStats()

Writes the statistics.

Parameters

plspace	The size in bytes currently occupied
par	par = 0 after a splitmerge. par = 1 after merge to sortfile. par = 2 after the sort

current expression is to be found in AR.CurExpr. terms are in S->TermsLeft. S->GenTerms.

Definition at line 93 of file sort.c.

4.10.5.14 PutPreVar()

Inserts/Updates a preprocessor variable in the name administration.

Parameters

name	Character string with the variable name.
value	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a?
args	Character string with possible arguments.
mode	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

Definition at line 713 of file pre.c.

4.10.5.15 CopyFile()

Copies a file with name *source to a file named *dest. The involved files must not be open. Returns non-zero if an error occurred. Uses if possible the combined large and small sorting buffers as cache.

Definition at line 1101 of file tools.c.

4.10.5.16 inicbufs()

```
int inicbufs ( VOID )
```

Creates a new compiler buffer and returns its ID number.

Returns

The ID number for the new compiler buffer.

Definition at line 47 of file comtool.c.

4.10.5.17 TheDefine()

```
int TheDefine ( \label{eq:UBYTE} \mbox{ $*$ $s$,} int \mbox{\it mode} )
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

s	Pointer to the character string following the preprocessor command.
mode	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit
	set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 2019 of file pre.c.

4.10.5.18 ComPress()

```
LONG ComPress ( \label{eq:word word word word word} \mbox{WORD ** $s$} s, LONG * $n$ )
```

Gets a list of pointers to terms and compresses the terms. In n it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

Parameters

ss Array of pointers to terms to be com		Array of pointers to terms to be compressed.
	n	Number of pointers in ss.

Returns

Total number of words needed for the compressed result.

Definition at line 3125 of file sort.c.

4.10.5.19 StageSort()

Prepares a stage 4 or higher sort. Stage 4 sorts occur when the sort file contains more patches than can be merged in one pass.

Definition at line 4514 of file sort.c.

4.10.5.20 DoubleCbuffer()

Doubles a compiler buffer.

Parameters

num	The ID number for the buffer to be doubled.	Ī
W	w The pointer to the end (exclusive) of the current buffer. The contents in the range of [cbuf[num].Buffer	
	will be kept.	

Definition at line 143 of file comtool.c.

4.10.5.21 AddLHS()

```
WORD* AddLHS (
          int num )
```

Adds an LHS to a compiler buffer and returns the pointer to a buffer for the new LHS.

Parameters

	num	The ID number for the buffer to get another LHS.	
--	-----	--	--

Definition at line 188 of file comtool.c.

4.10.5.22 AddRHS()

```
WORD* AddRHS (  \mbox{int } num, \\ \mbox{int } type \mbox{ })
```

Adds an RHS to a compiler buffer and returns the pointer to a buffer for the new RHS.

Parameters

num	The ID number for the buffer to get another RHS.
type	If 0, the subexpression tree will be reallocated.

Definition at line 214 of file comtool.c.

4.10.5.23 AddNtoL()

Adds an LHS with the given data to the current compiler buffer.

Parameters

n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 288 of file comtool.c.

4.10.5.24 AddNtoC()

```
int AddNtoC (
        int bufnum,
        int n,
        WORD * array,
        int par )
```

Adds the given data to the last LHS/RHS in a compiler buffer.

Parameters

bufnum	The ID number for the buffer where the data will be added.
n	The length of the data.
array	The data to be added.

Returns

0 if succeeds.

Definition at line 317 of file comtool.c.

4.10.5.25 TakeArgContent()

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. The common pieces are put in argout as a sequence of arguments. The part with the multiple terms that are now relative prime is put in argfree which is allocated via TermMalloc and is given as the return value. The difference with the old code is that negative powers are always removed. Hence it is as in MakeInteger in which only numerators will be left: now only zero or positive powers will be remaining.

Definition at line 2748 of file argument.c.

4.10.5.26 MakeInteger()

```
WORD* MakeInteger (
PHEAD WORD * argin,
WORD * argout,
WORD * argfree )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in argin. The number that comes out should go to argout. The new pointer in the argout buffer is the return value. The normalized argument is in argfree.

Definition at line 3294 of file argument.c.

4.10.5.27 MakeMod()

```
WORD* MakeMod (
          PHEAD WORD * argin,
          WORD * argout,
          WORD * argfree )
```

Similar to MakeInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3465 of file argument.c.

4.10.5.28 FindArg()

Looks the argument up in the (workers) table. If it is found the number in the table is returned (plus one to make it positive). If it is not found we look in the compiler provided table. If it is found - the number in the table is returned (minus one to make it negative). If in neither table we return zero.

Definition at line 2495 of file argument.c.

4.10.5.29 InsertArg()

```
WORD InsertArg (

PHEAD WORD * argin,

WORD * argout,

int par )
```

Inserts the argument into the (workers) table. If the table is too full we eliminate half of it. The eliminated elements are the ones that have not been used most recently, weighted by their total use and age(?). If par == 0 it inserts in the regular factorization cache If par == 1 it inserts in the cache defined with the FactorCache statement

Definition at line 2519 of file argument.c.

4.10.5.30 CleanupArgCache()

Cleans up the argument factorization cache. We throw half the elements. For a weight of what we want to keep we use the product of usage and the number in the buffer.

Definition at line 2554 of file argument.c.

4.10.5.31 SortWeights()

```
void SortWeights (
    LONG * weights,
    LONG * extraspace,
    WORD number )
```

Sorts an array of LONGS in the same way SplitMerge (in sort.c) works We use gradual division in two.

Definition at line 3510 of file argument.c.

4.10.5.32 MakeDollarInteger()

```
WORD* MakeDollarInteger (

PHEAD WORD * bufin,

WORD ** bufout )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3618 of file dollar.c.

4.10.5.33 MakeDollarMod()

```
WORD* MakeDollarMod (

PHEAD WORD * buffer,

WORD ** bufout )
```

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3792 of file dollar.c.

4.10.5.34 AddPotModdollar()

Adds a \$-variable specified by *numdollar* to the list of potentially modified \$-variables unless it has already been included in the list.

Parameters

numdollar The index of	the \$-variable to be added.
------------------------	------------------------------

Definition at line 3950 of file dollar.c.

4.10.5.35 Optimize()

Optimization of expression

4.10.6 Description

This method takes an input expression and generates optimized code to calculate its value. The following methods are called to do so:

- (1) get expression: to read to expression
- (2) get_brackets : find brackets for simultaneous optimization
- (3) occurrence_order or find_Horner_MCTS : to determine (the) Horner scheme(s) to use; this depends on AO. ← optimize.horner
- (4) optimize_expression_given_Horner: to do the optimizations for each Horner scheme; this method does either CSE or greedy optimizations dependings on AO.optimize.method
- (5) generate_output : to format the output in Form notation and store it in a buffer
- (6a) optimize_print_code : to print the expression (for "Print") or (6b) generate_expression : to modify the expression (for "#Optimize")

On ParFORM, all the processes must call this function at the same time. Then

- (1) Because only the master can access to the expression to be optimized, the master broadcast the expression to all the slaves after reading the expression (PF_get_expression).
- (2) get_brackets reads optimize_expr as the input and it works also on the slaves. We leave it although the bracket information is not needed on the slaves (used in (5) on the master).
- (3) and (4) find_Horner_MCTS and optimize_expression_given_Horner are parallelized.
- (5), (6a) and (6b) are needed only on the master.

Definition at line 4609 of file optimize.cc.

4.10.6.1 finishcbuf()

```
void finishcbuf ( WORD num )
```

Frees a compiler buffer.

Parameters

num The ID number for the buffer to be freed	i.
--	----

Definition at line 89 of file comtool.c.

4.10.6.2 clearcbuf()

```
void clearcbuf ( $\operatorname{\mathtt{WORD}}\ num )
```

Clears contents in a compiler buffer.

Parameters

```
num The ID number for the buffer to be cleared.
```

Definition at line 116 of file comtool.c.

4.10.6.3 CleanUpSort()

```
void CleanUpSort (
     int num )
```

Partially or completely frees function sort buffers.

Definition at line 4705 of file sort.c.

4.10.6.4 LowerSortLevel()

Lowers the level in the sort system.

Definition at line 4788 of file sort.c.

4.10.6.5 EvalDoLoopArg()

```
WORD EvalDoLoopArg (

PHEAD WORD * arg,

WORD par )
```

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRES-SIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER,num DOLLAREXPRESSION,numdollar DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor DOLLAREXPRESSION,numdollar,DOLLAREXPR2,numfactor,DOLLAREXPR2,numfactor etc. Because we have a doloop at every stage we should have a number. The notation in DOLLAREXPR2 is that >= 0 is number of yet another dollar and < 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

Definition at line 2642 of file dollar.c.

4.10.6.6 SymbolNormalize()

```
int Symbol
Normalize ( \label{eq:word} \mbox{WORD} \; * \; term \; )
```

Routine normalizes terms that contain only symbols. Regular minimum and maximum properties are ignored.

We check whether there are negative powers in the output. This is not allowed.

Definition at line 5127 of file normal.c.

4.10.6.7 CompareSymbols()

```
WORD CompareSymbols (

PHEAD WORD * term1,

WORD * term2,

WORD par )
```

Compares the terms, based on the value of AN.polysortflag. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 3029 of file sort.c.

4.10.6.8 CompareHSymbols()

```
WORD CompareHSymbols (

PHEAD WORD * term1,

WORD * term2,

WORD par )
```

Compares terms that can have only SYMBOL and HAAKJE subterms. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 3072 of file sort.c.

4.10.6.9 NextPrime()

```
WORD NextPrime ( {\tt PHEAD\ WORD\ \it num\ )}
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

Definition at line 3664 of file reken.c.

4.10.6.10 ReadSaveHeader()

```
WORD ReadSaveHeader ( VOID )
```

Reads the header in the save file and sets function pointers and flags according to the information found there. Must be called before any other ReadSave... function.

Currently works only for the exchange between 32bit and 64bit machines (WORD size must be 2 or 4 bytes)!

It is called by CoLoad().

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4050 of file store.c.

4.10.6.11 ReadSaveIndex()

```
WORD ReadSaveIndex ( FILEINDEX * fileind )
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

Parameters

fileind contains the read FILEINDEX after successful return. must point to	allocated, big enough memory.
--	-------------------------------

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4168 of file store.c.

4.10.6.12 ReadSaveExpression()

```
WORD ReadSaveExpression (

UBYTE * buffer,

UBYTE * top,

LONG * size,

LONG * outsize )
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word size (32bit at the moment). The actual renumbering is then done by calling the function ReadSaveTerm32(). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

Parameters

buffer	output buffer, holds the (translated) expression
top	end of buffer
size	number of read bytes
outsize	number of written bytes

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5131 of file store.c.

4.10.6.13 ReadSaveTerm32()

```
UBYTE * binend,

UBYTE ** bout,

UBYTE * boutend,

UBYTE * top,

int terminbuf)
```

Reads a single term from the given buffer at bin and write the translated term back to this buffer at bout.

ReadSaveTerm32() is currently the only instantiation of a ReadSaveTerm-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer AR.CompressBuffer.

The function is reentrant in order to cope with nested function arguments. It is called by ReadSaveExpression() and itself

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

Parameters

bin	start of the input buffer
binend	end of the input buffer
bout	as input points to the beginning of the output buffer, as output points behind the already translated data in the output buffer
boutend	end of already decompressed data in output buffer
top	end of output buffer
terminbuf	flag whether decompressed data is already in the output buffer. used in recursive calls

Returns

pointer to the next unprocessed data in the input buffer

Definition at line 4721 of file store.c.

4.10.6.14 ReadSaveVariables()

```
WORD ReadSaveVariables (

UBYTE * buffer,

UBYTE * top,

LONG * size,

LONG * outsize,

INDEXENTRY * ind,

LONG * stage )
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the *size bytes and writes them to the *buffer. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then *size is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in *size, the number of written bytes is returned in *outsize.

If the *size is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When ReadSaveVariables() is called for the first time, this parameter should have the value -1.

The parameter ind is used to get the number of variables.

Parameters

buffer	read variables are written into this allocated memory
top	upper end of allocated memory
size	number of bytes to read. might return a smaller number of read bytes if translation was necessary
outsize	if translation has be done, outsize contains the number of written bytes
ind	pointer of INDEXENTRY for the current expression. read-only
stage	should be -1 for the first call, will be increased by ReadSaveVariables to memorize the position in the variable structure

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4354 of file store.c.

4.10.6.15 WriteStoreHeader()

```
WORD WriteStoreHeader ( \label{eq:word_power} \mbox{WORD } \mbox{\it handle} \mbox{\it )}
```

Writes header with information about system architecture and FORM revision to an open store file.

Called by SetFileIndex().

Parameters

handle

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 3957 of file store.c.

4.10.6.16 InitRecovery()

Sets up the strings for the filenames of the recovery files. This functions should only be called once to avoid memory leaks and after AM.TempDir has been initialized.

Definition at line 399 of file checkpoint.c.

4.10.6.17 CheckRecoveryFile()

Checks whether a snapshot/recovery file exists. Returns 1 if it exists, 0 otherwise.

Definition at line 278 of file checkpoint.c.

4.10.6.18 DeleteRecoveryFile()

Deletes the recovery files. It is called by CleanUp() in the case of a successful completion.

Definition at line 333 of file checkpoint.c.

4.10.6.19 RecoveryFilename()

Returns pointer to recovery filename.

Definition at line 364 of file checkpoint.c.

4.10.6.20 DoRecovery()

```
int DoRecovery (
    int * moduletype )
```

Reads from the recovery file and restores all necessary variables and states in FORM, so that the execution can recommence in preprocessor() as if no restart of FORM had occurred.

The recovery file is read into memory as a whole. The pointer p then points into this memory at the next non-processed data. The macros by which variables are restored, like R_SET, automatically increase p appropriately.

If something goes wrong, the function returns with a non-zero value.

Allocated memory that would be lost when overwriting the global structs with data from the file is freed first. A major part of the code deals with the restoration of pointers. The idiom we use is to memorize the original pointer value (org), allocate new memory and copy the data from the file into this memory, calculate the offset between the old pointer value and the new allocated memory position (ofs), and then correct all affected pointers (+=ofs).

We rely on the fact that several variables (especially in AM) are already assigned the correct values by the startup functions. That means, in principle, that a change in the setup files between snapshot creation and recovery will be noticed.

Definition at line 1401 of file checkpoint.c.

4.10.6.21 DoCheckpoint()

```
void DoCheckpoint (
          int moduletype )
```

Checks whether a snapshot should be done. Calls DoSnapshot() to create the snapshot.

Definition at line 3108 of file checkpoint.c.

References TimeWallClock().

4.10.6.22 TestTerm()

```
int TestTerm ( \label{eq:word_word} \mbox{WORD} \ * \ term \ )
```

Tests the consistency of the term. Returns 0 when the term is OK. Any nonzero value is trouble. In the current version the testing isn't 100% complete. For instance, we don't check the validity of the symbols nor do we check the range of their powers. Etc. This should be extended when the need is there.

Parameters

```
term the term to be tested
```

Definition at line 3861 of file tools.c.

4.10.6.23 LocalConvertToPoly()

```
int LocalConvertToPoly (
          PHEAD WORD * term,
          WORD * outterm,
          WORD startebuf,
          WORD par )
```

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

Definition at line 510 of file notation.c.

4.10.6.24 IniFbuffer()

Initialize a factorization cache buffer. We set the size of the rhs and boomlijst buffers immediately to their final values.

Definition at line 614 of file comtool.c.

4.10.6.25 TakeSymbolContent()

```
WORD* TakeSymbolContent (
          PHEAD WORD * in,
          WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. Output: term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

Definition at line 2434 of file ratio.c.

```
WORD* TakeContent (
          PHEAD WORD * in,
           WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

Definition at line 1376 of file ratio.c.

4.10.6.27 poly_gcd()

```
WORD* poly_gcd (

PHEAD WORD * a,

WORD * b,

WORD fit )
```

Polynomial gcd

4.10.7 Description

This method calculates the greatest common divisor of two polynomials, given by two zero-terminated Form-style term lists.

4.10.8 Notes

- · The result is written at newly allocated memory
- · Called from ratio.c
- · Calls polygcd::gcd

Definition at line 124 of file polywrap.cc.

4.10.8.1 poly_ratfun_add()

Addition of PolyRatFuns

4.10.9 Description

This method gets two pointers to polyratfuns with up to two arguments each and calculates the sum.

4.10.10 Notes

- · The result is written at the workpointer
- · Called from sort.c and threads.c
- Calls poly::operators and polygcd::gcd

Definition at line 600 of file polywrap.cc.

4.10.10.1 poly_ratfun_normalize()

Multiplication/normalization of PolyRatFuns

4.10.11 Description

This method seaches a term for multiple polyratfuns and multiplies their contents. The result is properly normalized. Normalization also works for terms with a single polyratfun.

4.10.12 Notes

- · The result overwrites the original term
- Called from proces.c
- · Calls poly::operators and polygcd::gcd

Definition at line 719 of file polywrap.cc.

4.10.12.1 poly_factorize_argument()

```
int poly_factorize_argument (
          PHEAD WORD * argin,
          WORD * argout )
```

Factorization of function arguments

4.10.13 Description

This method factorizes the Form-style argument argin.

4.10.14 Notes

- · The result is written at argout
- Called from argument.c
- · Calls poly_factorize

Definition at line 1047 of file polywrap.cc.

4.10.14.1 poly_factorize_dollar()

Factorization of dollar variables

4.10.15 Description

This method factorizes a dollar variable.

4.10.16 Notes

- · The result is written at newly allocated memory.
- · Called from dollar.c
- · Calls poly_factorize

Definition at line 1074 of file polywrap.cc.

4.10.16.1 poly_factorize_expression()

Factorization of expressions

4.10.17 Description

This method factorizes an expression.

4.10.18 Notes

- The result overwrites the input expression
- Called from proces.c
- · Calls polyfact::factorize

Definition at line 1100 of file polywrap.cc.

4.10.18.1 optimize_print_code()

Print optimized code

4.10.19 Description

This method prints the optimized code via "PrintExtraSymbol". Depending on the flag, the original expression is printed (for "Print") or not (for "#Optimize / #write "O").

Definition at line 4496 of file optimize.cc.

4.10.19.1 DoPreAppendPath()

```
int DoPreAppendPath ( {\tt UBYTE} \ * \ s \ )
```

Appends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #appendpath <path>

Definition at line 7105 of file pre.c.

4.10.19.2 DoPrePrependPath()

```
int DoPrePrependPath ( {\tt UBYTE} \ * \ s \ )
```

Prepends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #prependpath <path>

Definition at line 7122 of file pre.c.

4.11 diagrams.c File Reference

```
#include "form3.h"
```

Functions

- int CoCanonicalize (UBYTE *s)
- int DoCanonicalize (PHEAD WORD *term, WORD *params)
- int DoTopologyCanonicalize (PHEAD WORD *term, WORD vert, WORD edge, WORD *args)
- int DoShattering (PHEAD WORD *connect, WORD *environ, WORD *partitions, WORD nvert)

4.11.1 Detailed Description

Contains the wrapper routines for diagram manipulations.

4.12 dict.c File Reference 235

- LONG DictToBytes (DICTIONARY *dict, UBYTE *buf)
- DICTIONARY * DictFromBytes (UBYTE *buf)

4.12.1 Detailed Description

Contains the code pertaining to dictionaries Commands are: #opendictionary name #closedictionary #selectdictionary name <options> There can be several dictionaries, but only one can be active. Defining elements is done with #add object: "replacement" Replacements are strings when a dictionary is for output translation. Objects can be 1: a number (rational) 2: a variable 3: $*^{\land}$ 4: a function with arguments

4.13.1 Detailed Description

The routines that deal with the dollar variables. The name administration is to be found in the file names.c

4.13.2 Macro Definition Documentation

4.13 dollar.c File Reference 237

4.13.2.1 STEP2

```
#define STEP2
```

Factors a dollar expression. Notation: d->nfactors becomes nonzero. if the number of factors is one, we leave d->factors zero. Otherwise factors is an array of pointers to the factors. These are pointers of the type FAC-DOLLAR. fd->where pointer to contents in term notation fd->size size of the buffer fd->where points to fd->type DOLNUMBER or DOLTERMS fd->value value if type is DOLNUMBER and it fits in a WORD.

Definition at line 2944 of file dollar.c.

4.13.3 Function Documentation

4.13.3.1 EvalDoLoopArg()

Evaluates one argument of a do loop. Such an argument is constructed from SNUMBERs DOLLAREXPRES-SIONs and possibly DOLLAREXPR2s which indicate factors of the preceeding dollar. Hence we have SNUMBER, num DOLLAREXPRESSION, numdollar DOLLAREXPRESSION, numdollar, DOLLAREXPR2, numfactor DOLLAREXPRESSION, numdollar, DOLLAREXPR2, numfactor, DOLLAREXPR2, numfactor etc. Because we have a doloop at every stage we should have a number. The notation in DOLLAREXPR2 is that \geq 0 is number of yet another dollar and < 0 is -n-1 with n the array element or zero. The return value is the (short) number. The routine works its way through the list in a recursive manner.

Definition at line 2642 of file dollar.c.

4.13.3.2 MakeDollarInteger()

```
WORD* MakeDollarInteger (
PHEAD WORD * bufin,
WORD ** bufout )
```

For normalizing everything to integers we have to determine for all elements of this argument the LCM of the denominators and the GCD of the numerators. The input argument is in bufin. The number that comes out is the return value. The normalized argument is in bufout.

Definition at line 3618 of file dollar.c.

4.13.3.3 MakeDollarMod()

Similar to MakeDollarInteger but now with modulus arithmetic using only a one WORD 'prime'. We make the coefficient of the first term in the argument equal to one. Already the coefficients are taken modulus AN.cmod and AN.ncmod == 1

Definition at line 3792 of file dollar.c.

4.13.3.4 AddPotModdollar()

Adds a \$-variable specified by *numdollar* to the list of potentially modified \$-variables unless it has already been included in the list.

Parameters

numdollar The index of the \$-variable	to be added.
--	--------------

Definition at line 3950 of file dollar.c.

- WORD FindOnce (PHEAD WORD *term, WORD *pattern)
- WORD FindMulti (PHEAD WORD *term, WORD *pattern)
- WORD FindRest (PHEAD WORD *term, WORD *pattern)

4.17.1 Detailed Description

Pattern matching of symbols and dotproducts. There are various routines because of the options in the idstatements like once, only, multi and many. These are amoung the oldest routines in FORM and that can be noticed, because the interplay with the function matching is not complete. When we match functions and halfway we fail we can backtrack properly. With the symbols, the dotproducts and the vectors (in pattern.c) there is no proper backtracking. Hence the routines here need still quite some work or may even have to be rewritten.

4.18.1 Detailed Description

This file contains numerical routines that deal with floating point numbers. We use the GMP for arbitrary precision floating point arithmetic. The functions of the type sin, cos, ln, sqrt etc are handled by the mpfr library. The reason that for MZV's and the general notation we use the GMP (mpf_) is because the contents of the structs have been frozen and can be used for storage in a Form function float_. With mpfr_ this is not safely possible. All mpfr_ related code is in the file evaluate.c.

4.21.1 Detailed Description

Contains the definitions of many internal codes Rather than using numbers directly we do this by defines, making it much easier to change things. Changing things is sometimes also a good way of testing the code.

4.21.2 Macro Definition Documentation

4.21.2.1 WITHOUTERROR

```
#define WITHOUTERROR 0
```

The next macros were introduced when TFORM was programmed. In the case of workers, each worker may need some private data. These can in principle be accessed by some posix calls but that is unnecessarily slow. The passing of a pointer to the complete data struct with private data will be much faster. And anyway, there would have to be a macro that either makes the posix call (TFORM) or doesn't (FORM). The solution by having macro's that either pass the pointer (TFORM) or don't pass it (FORM) is seen as the best solution.

In the declarations and the calling of the functions we have to use the PHEAD or the BHEAD macro, respectively, if the pointer is to be passed. These macro's contain the comma as well. Hence we need special macro's if there are no other arguments. These are called PHEAD0 and BHEAD0.

Definition at line 51 of file ftypes.h.

4.22 function.c File Reference

```
#include "form3.h"
```

Functions

- WORD MakeDirty (WORD *term, WORD *x, WORD par)
- void MarkDirty (WORD *term, WORD flags)
- void PolyFunDirty (PHEAD WORD *term)
- void PolyFunClean (PHEAD WORD *term)

4.32.1 Detailed Description

MPI dependent functions of parform

This file contains all the functions for the parallel version of form3 that explicitly need to call mpi routines. This is the only file that really needs to be linked to the mpi-library!

4.32.2 Macro Definition Documentation

4.32.2.1 MPI_ERRCODE_CHECK

A macro which exits the caller with a non-zero return value if *err* is not MPI_SUCCESS.

Parameters

err The return value of a MPI function to be checked.

Remarks

The MPI standard defines MPI_SUCCESS == 0. Then (_tmp_err == 0) appears twice and we can expect the second evaluation will be eliminated by the compiler optimization.

Definition at line 84 of file mpi.c.

4.32.3 Function Documentation

4.32.3.1 PF_RealTime()

```
LONG PF_RealTime (  \qquad \qquad \text{int } i \ ) \\
```

Returns the realtime in 1/100 sec. as a LONG.

Parameters

```
i the timer will be reset if i == 0.
```

Returns

the real elapsed time in 1/100 second.

Definition at line 101 of file mpi.c.

4.32.3.2 PF_LibInit()

```
int PF_LibInit (
                int * argcp,
                char *** argvp )
```

Performs all library dependent initializations.

Parameters

argcp	pointer to the number of arguments.
argvp	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 123 of file mpi.c.

4.32.3.3 PF_LibTerminate()

Exits mpi, when there is an error either indicated or happening, returnvalue is 1, else returnvalue is 0.

Parameters

```
error an error code.
```

Returns

0 if OK, nonzero on error.

Definition at line 209 of file mpi.c.

Referenced by PF_Terminate().

4.32.3.4 PF_Probe()

Probes the next incoming message. If src == PF_ANY_SOURCE this operation is blocking, otherwise nonbloking.

Parameters

in,out	src	the source process number. In output, the process number of actual found source.
--------	-----	--

Returns

the tag value of the next incoming message if found, 0 if a nonbloking probe (input src != PF_ANY_SOURCE) did not find any messages. A negative returned value indicates an error.

Definition at line 230 of file mpi.c.

4.32.3.5 PF_ISendSbuf()

```
int PF_ISendSbuf (  \qquad \qquad \text{int $to$,} \\ \qquad \qquad \text{int $tag$ )}
```

Nonblocking send operation. It sends everything from <code>buff</code> to <code>fill</code> of the active buffer. Depending on *tag* it also can do waiting for other sends to finish or set the active buffer to the next one.

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 261 of file mpi.c.

4.32.3.6 PF_RecvWbuf()

```
int PF_RecvWbuf ( \label{eq:word * b, Long * s, Long * s, int * src }
```

Blocking receive of a WORD buffer.

Parameters

out b the buffer to store the received data.		the buffer to store the received data.
in,out	s	the size of the buffer. The output value is the actual size of the received data.
in,out	src	the source process number. The output value is the process number of actual source.

Returns

the received message tag. A negative value indicates an error.

Definition at line 337 of file mpi.c.

4.32.3.7 PF_IRecvRbuf()

Posts nonblocking receive for the active receive buffer. The buffer is filled from full to stop.

Parameters

r	the PF_BUFFER struct for the nonblocking receive.
bn	the index of the cyclic buffer.
from	the source process number.

Returns

0 if OK, nonzero on error.

Definition at line 366 of file mpi.c.

4.32.3.8 PF_WaitRbuf()

Waits for the buffer bn to finish a pending nonblocking receive. It returns the received tag and in *size the number of field received. If the receive is already finished, just return the flag and size, else wait for it to finish, but also check for other pending receives.

Parameters

		r	the PF_BUFFER struct for the pending nonblocking receive.
ĺ		bn	the index of the cyclic buffer.
Ī	out	size	the actual size of received data.

Returns

the received message tag. A negative value indicates an error.

Definition at line 400 of file mpi.c.

4.32.3.9 PF_Bcast()

```
int PF_Bcast (
     void * buffer,
     int count )
```

Broadcasts a message from the master to slaves.

Parameters

in,out	buffer	the starting address of buffer. The contents in this buffer on the master will be transferred	
		to those on the slaves.	
	count	the length of the buffer in bytes.	1

Returns

0 if OK, nonzero on error.

Definition at line 440 of file mpi.c.

4.32.3.10 PF_RawSend()

```
int PF_RawSend (
    int dest,
    void * buf,
    LONG 1,
    int tag )
```

Sends I bytes from buf to dest. Returns 0 on success, or -1.

Parameters

dest	the destination process number.
buf	the send buffer.
1	the size of data in the send buffer in bytes.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 463 of file mpi.c.

Referenced by PF_SendFile().

4.32.3.11 PF_RawRecv()

Receives not more than *thesize* bytes from *src*, returns the actual number of received bytes, or -1 on failure.

Parameters

in,out	src	the source process number. In output, that of the actual received message.
out	buf	the receive buffer.
	thesize	the size of the receive buffer in bytes.
out	tag	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 484 of file mpi.c.

4.32.3.12 PF_RawProbe()

```
int PF_RawProbe (
    int * src,
    int * tag,
    int * bytesize )
```

Probes an incoming message.

Parameters

in,out	src	the source process number. In output, that of the actual received message.
in,out	tag	the message tag. In output, that of the actual received message.
out	bytesize	the size of incoming data in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 508 of file mpi.c.

4.32.3.13 PF_PrintPackBuf()

Prints the contents in the pack buffer.

Parameters

s	a message to be shown.
size	the length of the buffer to be shown.

Generated by Doxygen

Returns

0 if OK, nonzero on error.

Definition at line 594 of file mpi.c.

4.32.3.14 PF_PreparePack()

```
int PF_PreparePack (
     void )
```

Prepares for the next pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 624 of file mpi.c.

4.32.3.15 PF_Pack()

Adds data into the pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 642 of file mpi.c.

4.32.3.16 PF_Unpack()

```
int PF_Unpack (
     void * buffer,
```

```
size_t count,
MPI_Datatype type )
```

Retrieves the next data in the pack buffer.

Parameters

out		the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 671 of file mpi.c.

4.32.3.17 PF_PackString()

Packs a string *str* into the packed buffer PF packbuf, including the trailing zero.

The first element (PF_INT) is the length of the packed portion of the string. If the string does not fit to the buffer PF← _packbuf, the function packs only the initial portion. It returns the number of packed bytes, so if (str[length-1]=='\0') then the whole string fits to the buffer, if not, then the rest (str+length) bust be packed and send again. On error, the function returns the negative error code.

One exception: the string "\0!\0" is used as an image of the NULL, so all 3 characters will be packed.

Parameters

```
str a string to be packed.
```

Returns

the number of packed bytes, or a negative value on failure.

Definition at line 706 of file mpi.c.

4.32.3.18 PF_UnpackString()

```
int PF_UnpackString ( {\tt UBYTE} \ * \ str \ )
```

Unpacks a string to str from the packed buffer PF_packbuf, including the trailing zero.

It returns the number of unpacked bytes, so if (str[length-1]=="\0') then the whole string was unpacked, if not, then the rest must be appended to (str+length). On error, the function returns the negative error code.

Parameters

out

Returns

the number of unpacked bytes, or a negative value on failure.

Definition at line 774 of file mpi.c.

4.32.3.19 PF_Send()

Sends the contents in the pack buffer to the process specified by to.

Example:

```
if ( PF.me == SRC ) {
    PF_PreparePack();
    // Packing operations here...
    PF_Send(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_Receive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
```

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 822 of file mpi.c.

4.32.3.20 PF_Receive()

```
int PF_Receive (
    int src,
    int tag,
    int * psrc,
    int * ptag )
```

Receives data into the pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_Send().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	psrc	the actual source process number of received message.
out	ptag	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 848 of file mpi.c.

4.32.3.21 PF_Broadcast()

```
int PF_Broadcast (
     void )
```

Broadcasts the contents in the pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PreparePack();
    // Packing operations here...
}
PF_Broadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 883 of file mpi.c.

4.32.3.22 PF_PrepareLongSinglePack()

Prepares for the next long-single-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1451 of file mpi.c.

4.32.3.23 PF_LongSinglePack()

Adds data into the "long single" pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.	
count	the number of elements in the buffer.	
type	the data type of elements in the buffer.	

Returns

0 if OK, nonzero on error.

Definition at line 1469 of file mpi.c.

4.32.3.24 PF_LongSingleUnpack()

Retrieves the next data in the "long single" pack buffer.

Parameters

out		the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1503 of file mpi.c.

4.32.3.25 PF_LongSingleSend()

```
int PF_LongSingleSend (  \qquad \qquad \text{int $to$,} \\ \qquad \qquad \text{int $tag$ )}
```

Sends the contents in the "long single" pack buffer to the process specified by to.

Example:

```
if ( PF.me == SRC ) {
    PF_PrepareLongSinglePack();
    // Packing operations here...
    PF_LongSingleSend(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_LongSingleReceive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
}
```

Parameters

to	the destination process number.	
tag	the message tag.	

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file mpi.c.

4.32.3.26 PF_LongSingleReceive()

Receives data into the "long single" pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_LongSingleSend().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	psrc	the actual source process number of received message.
out	ptag	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1583 of file mpi.c.

4.32.3.27 PF_PrepareLongMultiPack()

```
\label{eq:prepareLongMultiPack} \mbox{int PF\_PrepareLongMultiPack (} \\ \mbox{void )}
```

Prepares for the next long-multi-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1643 of file mpi.c.

4.32.3.28 PF_LongMultiPackImpl()

Adds data into the "long multi" pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.		
count	the number of elements in the buffer.		
eSize	the byte size of each element of data.		
type	the data type of elements in the buffer.		

Returns

0 if OK, nonzero on error.

Definition at line 1662 of file mpi.c.

4.32.3.29 PF_LongMultiUnpackImpl()

```
int PF_LongMultiUnpackImpl (
    void * buffer,
    size_t count,
    size_t eSize,
    MPI_Datatype type )
```

Retrieves the next data in the "long multi" pack buffer.

Parameters

out	buffer	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	eSize	the byte size of each element of data.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1721 of file mpi.c.

4.32.3.30 PF_LongMultiBroadcast()

Broadcasts the contents in the "long multi" pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PrepareLongMultiPack();
    // Packing operations here...
}
PF_LongMultiBroadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 1807 of file mpi.c.

- int TestFunFlag (PHEAD WORD *tfun)
- WORD BracketNormalize (PHEAD WORD *term)

4.35.1 Detailed Description

Mainly the routine Normalize. This routine brings terms to standard FORM. Currently it has one serious drawback. Its buffers are all in the stack. This means these buffers have a fixed size (NORMSIZE). In the past this has caused problems and NORMSIZE had to be increased.

It is not clear whether Normalize can be called recursively.

4.35.2 Function Documentation

4.35.2.1 SymbolNormalize()

```
int Symbol
Normalize ( \label{eq:word} \mbox{WORD} \; * \; term \; )
```

Routine normalizes terms that contain only symbols. Regular minimum and maximum properties are ignored.

We check whether there are negative powers in the output. This is not allowed.

Definition at line 5127 of file normal.c.

4.36 notation.c File Reference

- void PrintExtraSymbol (int num, WORD *terms, int par)
- WORD FindSubexpression (WORD *subexpr)
- int ExtraSymFun (PHEAD WORD *term, WORD level)
- int PruneExtraSymbols (WORD downto)

4.36.1 Detailed Description

Contains the functions that deal with the rewriting and manipulation of expressions/terms in polynomial representation.

4.36.2 Function Documentation

4.36.2.1 LocalConvertToPoly()

```
int LocalConvertToPoly (
          PHEAD WORD * term,
          WORD * outterm,
          WORD startebuf,
          WORD par )
```

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

Definition at line 510 of file notation.c.

4.38.1 Detailed Description

experimental routines for the optimization of FORTRAN or C output.

4.38.2 Function Documentation

4.38.2.1 my_random_shuffle()

Random shuffle

4.38.3 Description

Randomly permutes elements in the range [fr,to). Functionality is the same as C++'s "random_shuffle", but it uses Form's "wranf".

Definition at line 184 of file optimize.cc.

4.38.3.1 get_expression()

```
LONG get_expression ( int exprnr )
```

Get expression

4.38.4 Description

Reads an expression from the input file into a buffer (called optimize_expr). This buffer is used during the optimization process. Non-symbols are removed by ConvertToPoly and are put in temporary symbols.

The return value is the length of the expression in WORDs, or a negative number if it failed.

Definition at line 208 of file optimize.cc.

4.38.4.1 get_brackets()

```
vector<vector<WORD> > get_brackets ( )
```

Get brackets

4.38.5 Description

Checks whether the input expression (stored in optimize_expr) contains brackets. If so, this method replaces terms outside brackets by powers of SEPERATESYMBOL (equal brackets have equal powers) and the brackets are returned. If not, the result is empty.

Brackets are used for simultaneous optimization. The symbol SEPARATESYMBOL is always the first one used in a Horner scheme.

Definition at line 285 of file optimize.cc.

4.38.5.1 count_operators() [1/2]

Count operators

4.38.6 Description

Counts the number of operators in a Form-style expression.

Definition at line 405 of file optimize.cc.

Referenced by optimize_greedy().

4.38.6.1 count_operators() [2/2]

Count operators

4.38.7 Description

Counts the number of operators in a vector of instructions

Definition at line 459 of file optimize.cc.

4.38.7.1 occurrence_order()

Occurrence order

4.38.8 Description

Extracts all variables from an expression and sorts them with most occurring first (or last, with rev=true)

Definition at line 502 of file optimize.cc.

4.38.8.1 getpower()

Horner tree building

4.38.9 Description

Given a Form-style expression (in a buffer in memory), this builds an expression tree. The tree is determined by a multivariate Horner scheme, i.e., something of the form:

```
1+y+x*(2+y*(1+y)+x*(3-y*(...)))
```

The order of the variables is given to the method "Horner_tree", which renumbers ad reorders the terms of the expression. Next, the recursive method "build_Horner_tree" does the actual tree construction.

The tree is represented in postfix notation. Tokens are of the following forms:

- · SNUMBER tokenlength num den coefflength
- · SYMBOL tokenlength variable power
- OPER_ADD or OPER_MUL

4.38.10 Note

Sets AN.poly_num_vars and allocates AN.poly_vars. The latter should be freed later. Get power of variable (helper function for build_Horner_tree)

4.38.11 Description

Returns the power of the variable "var", which is at position "pos" in this term, if it is present.

Definition at line 583 of file optimize.cc.

4.38.11.1 fixarg()

```
void fixarg ( {\tt UWORD} \, * \, t \text{,} \\ {\tt WORD} \, \& \, n \, )
```

Call GcdLong/DivLong with leading zeroes

4.38.12 Description

These method remove leading zeroes, so that GcdLong and DivLong can safely be called.

Definition at line 597 of file optimize.cc.

4.38.12.1 build_Horner_tree()

Build the Horner tree

4.38.13 Description

Constructs the Horner tree. The method processes one variable and continues recursively until the Horner scheme is completed.

"terms" is a pointer to the starts of the terms. "numterms" is the number of terms to be processed. "var" is the next variable to be processed (index between 0 and #maxvar) and "maxvar" is the last variable to be processed, so that partial Horner trees can also be constructed. "pos" is the position that the power of "var" should be in (one level further in the recursion, "pos" has increased by 0 or 1 depending on whether the previous power was 0 or not). The result is written at the pointer "res".

This method also factors out gcds of the coefficients. The result should end with "gcd OPER_MUL" at all times, so that one level higher gcds can be extracted again.

Definition at line 635 of file optimize.cc.

4.38.13.1 term_compare()

Term compare (helper function for Horner tree)

4.38.14 Description

Compares two terms of the form "L SYM 4 x n coeff" or "L coeff". Lower powers of lower-indexed symbols come first. This is used to sort the terms in correct order.

Definition at line 835 of file optimize.cc.

4.38.14.1 Horner_tree()

Prepare Horner tree building

4.38.15 Description

This method renumbers the variables to 0...#vars-1 according to the specified order. Next, it stored pointer to individual terms and sorts the terms with higher power first. Then the sorted lists of power is used for the construction of the Horner tree.

Definition at line 856 of file optimize.cc.

4.38.15.1 generate_instructions()

Generate instructions

4.38.16 Description

Converts the expression tree to a list of instructions that directly translate to code. Instructions are of the form:

expr.nr operator length [operands]+ trailing.zero

The operands are of the form:

length [(EXTRA)SYMBOL length variable power] coeff

This method only generates binary operators. Merging is done later. The method also checks for common subexpressions and eliminates them and the flag "do CSE" is set.

4.38.17 Implementation details

The map "ID" keeps track of which subexpressions already exist. The key is formatted as one of the following:

SYMBOL x n SNUMBER coeff OPERATOR LHS RHS

with LHS/RHS formatted as one of the following:

SNUMBER idx 0 (EXTRA)SYMBOL x n

ID[symbol] or ID[operator] equals a subexpression number. ID[coeff] equals the position of the number in the input.

The stack s is used the process the postfix expression tree. Three-word tokens of the form:

SNUMBER idx.of.coeff 0 SYMBOL x n EXTRASYMBOL x 1

are pushed onto it. Operators pop two operands and push the resulting expression.

(Extra)symbols are 1-indexed, because -X is also needed to represent -1 times this term.

There is currently a bug. The notation cannot tell if there is a single bracket and then ignores the bracket.

TODO: check if this method performs properly if do_CSE=false

Definition at line 1104 of file optimize.cc.

4.38.17.1 count_operators_cse()

Count number of operators in a binary tree, while removing CSEs on the fly. The instruction set is not created, which makes this method slightly faster.

A hash is created on the fly and is passed through the stack. TODO: find better hash functions

Definition at line 1313 of file optimize.cc.

4.38.17.2 find_Horner_MCTS()

```
void find_Horner_MCTS ( )
```

Find best Horner schemes using MCTS

4.38.18 Description

The method governs the MCTS for the best Horner schemes. It does some pre-processing, calls "find_Horner_

MCTS_expand_tree" a number of times and does some post-processing.

Definition at line 2226 of file optimize.cc.

4.38.18.1 merge_operators()

Merge operators

4.38.19 Description

The input instructions form a binary DAG. This method merges expressions like

```
Z1 = a+b; Z2 = Z1+c;
```

into

Z2 = a+b+c;

An instruction is merged iff it only has one parent and the operator equals its parent's operator.

This still leaves some freedom: where should the coefficients end up in cases as:

$$Z1 = Z2 + x \le Z1 = 2*Z2 + x Z2 = 2*x*y Z2 = x*y$$

Both are relevant, e.g. for CSE of the form "2*x" and "2*Z2". The flag "move_coeff" moves coefficients from LHS-like expressions to RHS-like expressions.

Furthermore, this method removes empty equation (Z1=0), that are introduced by some "optimize_greedy" substitutions.

4.38.20 Implementation details

Expressions are mostly traversed via a stack, so that parents are evaluated before their children.

With "move_coeff" set coefficients are moved, but this leads to some tricky cases, e.g.

```
Z1 = Z2 + x Z2 = 2*y
```

Here Z2 reduces to the trivial equation Z2=y, which should be eliminated. Here the array skip[i] comes in.

Furthermore in the case

```
Z1 = Z2 + x Z2 = 2*Z3 Z3 = x*Z4 Z4 = y*z
```

after substituting Z1 = 2*Z3 + x, the parent expression for Z4 becomes Z3 instead of Z2. This is where renum_par[i] comes in.

Finally, once a coefficient has been moved, skip_coeff[i] is set and this coefficient is copied into the new expression anymore.

Definition at line 2374 of file optimize.cc.

4.38.20.1 find_optimizations()

Find optimizations

4.38.21 Description

This method find all optimization of the form described in "class Optimization". It process every equation, looking for possible optimizations and stores them in a fast-access data structure to count the total improvement of an optimization.

Definition at line 2669 of file optimize.cc.

4.38.21.1 do_optimization()

Do optimization

4.38.22 Description

This method performs an optimization. It scans through the equations of "optim.eqnidxs" and looks in which this optimization can still be performed (due to other performed optimizations this isn't always the case). If possible, it substitutes the common subexpression by a new extra symbol numbered "newid". Finally, the new extrasymbol is defined accordingly.

Substitutions may lead to trivial equations of the form "Zi=Zj", but these are removed in the end of the method. The method returns whether the substitution has been done once or more (or not).

Definition at line 2902 of file optimize.cc.

4.38.22.1 partial factorize()

Partial factorization of instructions

4.38.23 Description

This method performs partial factorization of instructions. In particular the following instructions

```
Z1 = x*a*b Z2 = x*c*d*e Z3 = 2*x + Z1 + Z2 + more are replaced by
```

```
Z1 = a*b Z2 = c*d*e Z3 = Zj + more Zi = 2 + Z1 + Z2 Zj = x*Zi
```

Here it is necessary that no other equations refer to Z1 and Z2. The generation of trivial instructions (Zi=Zj or Zi=x) is prevented.

Definition at line 3451 of file optimize.cc.

4.38.23.1 optimize_greedy()

Optimize instructions greedily

4.38.24 Description

This method optimizes an expression greedily. It calls "find_optimizations" to obtain candidates and performs the best one(s) by calling "do_optimization".

How many different optimization are done, before "find_optimization" is called again, is determined by the settings "greedyminnum" and "greedymaxperc".

During the optimization process, sequences of zeroes are introduced in the instructions, since moving all instructions when one gets optimized, is very costly. Therefore, in the end, the instructions are "compressed" again to remove these extra zeroes.

Definition at line 3745 of file optimize.cc.

References count_operators().

4.38.24.1 recycle_variables()

```
\label{local_problem} $$ \ensuremath{\mathsf{vector}}\ensuremath{\mathsf{VORD}}\ensuremath{\mathsf{>}} \ensuremath{\ensuremath{\mathsf{e}}} \ensuremath{\ensuremath{\mathsf{all\_instr}}} \ensuremath{)} $$
```

Recycle variables

4.38.25 Description

The current input uses many temporary variables. Many of them become obsolete at some point during the evaluation of the code, so can be recycled. This method renumbers the temporary variables, so that they are recycled. Furthermore, the input is order in depth-first order, so that the instructions can be performed consecutively.

4.38.26 Implementation details

First, for each subDAG, an estimate for the number of variables needed is made. This is done by the following recursive formula:

```
\#vars(x) = max(\#vars(ch_i(x)) + i),
```

with ch_i(x) the i-th child of x, where the childs are ordered w.r.t. #vars(ch_i). This formula is exact if the input forms a tree, and otherwise gives a reasonable estimate.

Then, the instructions are reordered in a depth-first order with childs ordered w.r.t. #vars. Next, the times that variables become obsolete are found. Each LHS of an instruction is renumbered to the lowest-numbered temporary variable that is available at that time.

Definition at line 3885 of file optimize.cc.

4.38.26.1 optimize_expression_given_Horner()

```
void optimize_expression_given_Horner ( )
```

Optimize expression given a Horner scheme

4.38.27 Description

This method picks one Horner scheme from the list of best Horner schemes, applies this scheme to the expression and then, depending on optimize.settings, does a common subexpression elimination (CSE) or performs greedy optimizations.

CSE is fast, while greedy might be slow. CSE followed by greedy is faster than greedy alone, but typically results in slightly worse code (not proven; just observed). eventually do greedy optimations

Definition at line 4032 of file optimize.cc.

4.38.27.1 generate output()

Generate output

4.38.28 Description

This method prepares the instructions for printing. They are stored in Form format, so that they can be printed by "PrintExtraSymbol". The results are stored in the buffer AO.OptimizeResult.

Definition at line 4263 of file optimize.cc.

4.38.28.1 generate_expression()

```
WORD generate_expression ( \label{eq:word_exprn} \mbox{WORD } \mbox{\it exprnr} \mbox{\it )}
```

Generate expression

4.38.29 Description

This method modifies the original optimized expression by an expression with extra symbols. This is used for "#Optimize".

Definition at line 4416 of file optimize.cc.

4.38.29.1 optimize_print_code()

Print optimized code

4.38.30 Description

This method prints the optimized code via "PrintExtraSymbol". Depending on the flag, the original expression is printed (for "Print") or not (for "#Optimize / #write "O").

Definition at line 4496 of file optimize.cc.

4.38.30.1 Optimize()

Optimization of expression

4.38.31 Description

This method takes an input expression and generates optimized code to calculate its value. The following methods are called to do so:

- (1) get expression: to read to expression
- (2) get brackets: find brackets for simultaneous optimization
- (3) occurrence_order or find_Horner_MCTS : to determine (the) Horner scheme(s) to use; this depends on AO. ← optimize.horner
- (4) optimize_expression_given_Horner: to do the optimizations for each Horner scheme; this method does either CSE or greedy optimizations dependings on AO.optimize.method
- (5) generate output: to format the output in Form notation and store it in a buffer
- (6a) optimize_print_code : to print the expression (for "Print") or (6b) generate_expression : to modify the expression (for "#Optimize")
- On ParFORM, all the processes must call this function at the same time. Then
- (1) Because only the master can access to the expression to be optimized, the master broadcast the expression to all the slaves after reading the expression (PF_get_expression).
- (2) get_brackets reads optimize_expr as the input and it works also on the slaves. We leave it although the bracket information is not needed on the slaves (used in (5) on the master).
- (3) and (4) find Horner MCTS and optimize expression given Horner are parallelized.
- (5), (6a) and (6b) are needed only on the master.

Definition at line 4609 of file optimize.cc.

4.38.31.1 ClearOptimize()

```
int ClearOptimize ( )
```

Optimization of expression

4.38.32 Description

Clears the buffers that were used for optimization output. Clears the expression from the buffers (marks it to be dropped). Note: we need to use the expression by its name, because numbers may change if we drop other expressions between when we do the optimizations and clear the results (in execute.c). Also this is not 100% safe, because we could overwrite the optimized expression. But that can be done only in a Local or Global statement and hence we only have to test there that we might have to call ClearOptimize first. (in file comexpr.c)

Definition at line 4946 of file optimize.cc.

4.39.1 Detailed Description

Message passing library independent functions of parform

This file contains functions needed for the parallel version of form3 these functions need no real link to the message passing libraries, they only need some interface dependent preprocessor definitions (check parallel.h). So there still need two different objectfiles to be compiled for mpi and pvm!

4.39.2 Macro Definition Documentation

4.39.2.1 SWAP

Swaps the variables x and y. If sizeof(x) != sizeof(y) then a compilation error will occur. A set of memcpy calls with constant sizes is expected to be inlined by the optimisation.

Definition at line 124 of file parallel.c.

4.39.2.2 PACK LONG

Packs a LONG value n to a WORD buffer p.

Definition at line 135 of file parallel.c.

4.39.2.3 UNPACK_LONG

Unpacks a LONG value *n* from a WORD buffer *p*.

Definition at line 144 of file parallel.c.

4.39.2.4 CHECK

A simple check for unrecoverable errors.

Definition at line 153 of file parallel.c.

4.39.2.5 __CHECK

} \
} while (0)

Definition at line 155 of file parallel.c.

Terminate(-1); \

4.39.3 Typedef Documentation

4.39.3.1 NODE

```
typedef struct NoDe NODE
```

A node for the tree of losers in the final sorting on the master.

4.39.4 Function Documentation

4.39.4.1 PF_RealTime()

Returns the realtime in 1/100 sec. as a LONG.

Parameters

```
i the timer will be reset if i == 0.
```

Returns

the real elapsed time in 1/100 second.

Definition at line 101 of file mpi.c.

4.39.4.2 PF_LibInit()

Performs all library dependent initializations.

Parameters

argcp	pointer to the number of arguments.
argvp	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 123 of file mpi.c.

4.39.4.3 PF_LibTerminate()

```
int PF_LibTerminate (
          int error )
```

Exits mpi, when there is an error either indicated or happening, returnvalue is 1, else returnvalue is 0.

Parameters

```
error an error code.
```

Returns

0 if OK, nonzero on error.

Definition at line 209 of file mpi.c.

Referenced by PF_Terminate().

4.39.4.4 PF_Probe()

Probes the next incoming message. If src == PF_ANY_SOURCE this operation is blocking, otherwise nonbloking.

Parameters

	in,out	src	the source process number. In output, the process number of actual found source.
--	--------	-----	--

Returns

the tag value of the next incoming message if found, 0 if a nonbloking probe (input src != PF_ANY_SOURCE) did not find any messages. A negative returned value indicates an error.

Definition at line 230 of file mpi.c.

4.39.4.5 PF_RecvWbuf()

```
int PF_RecvWbuf ( \label{eq:word * b, Long * s, int * src}
```

Blocking receive of a WORD buffer.

Parameters

out	at b the buffer to store the received data.	
in,out	s	the size of the buffer. The output value is the actual size of the received data.
in,out	src	the source process number. The output value is the process number of actual source.

Returns

the received message tag. A negative value indicates an error.

Definition at line 337 of file mpi.c.

4.39.4.6 PF_IRecvRbuf()

Posts nonblocking receive for the active receive buffer. The buffer is filled from full to stop.

Parameters

r	the PF_BUFFER struct for the nonblocking receive.	
bn	the index of the cyclic buffer.	
from	om the source process number.	

Returns

0 if OK, nonzero on error.

Definition at line 366 of file mpi.c.

4.39.4.7 PF_WaitRbuf()

Waits for the buffer bn to finish a pending nonblocking receive. It returns the received tag and in *size the number of field received. If the receive is already finished, just return the flag and size, else wait for it to finish, but also check for other pending receives.

Parameters

	r	the PF_BUFFER struct for the pending nonblocking receive.
	bn	the index of the cyclic buffer.
out	size	the actual size of received data.

Returns

the received message tag. A negative value indicates an error.

Definition at line 400 of file mpi.c.

4.39.4.8 PF_RawSend()

```
int PF_RawSend (
    int dest,
    void * buf,
    LONG 1,
    int tag )
```

Sends / bytes from buf to dest. Returns 0 on success, or -1.

Parameters

dest	the destination process number.
buf	the send buffer.
1	the size of data in the send buffer in bytes.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 463 of file mpi.c.

Referenced by PF_SendFile().

4.39.4.9 PF_RawRecv()

```
LONG PF_RawRecv (
    int * src,
    void * buf,
    LONG thesize,
    int * tag )
```

Receives not more than thesize bytes from src, returns the actual number of received bytes, or -1 on failure.

Parameters

in,out	src	the source process number. In output, that of the actual received message.
out	buf	the receive buffer.
	thesize	the size of the receive buffer in bytes.
out	tag	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 484 of file mpi.c.

4.39.4.10 PF_RawProbe()

```
int PF_RawProbe (
    int * src,
    int * tag,
    int * bytesize )
```

Probes an incoming message.

Parameters

in,out	src	the source process number. In output, that of the actual received message.
in,out	tag	the message tag. In output, that of the actual received message.
out	bytesize	the size of incoming data in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 508 of file mpi.c.

4.39.4.11 PF_EndSort()

```
int PF_EndSort (
     void )
```

Finishes a master sorting with collecting terms from slaves. Called by EndSort().

If this is not the masterprocess, just initialize the sendbuffers and return 0, else PF_EndSort() sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' (PF_GetLoser()) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if EndSort() still must perform a regular sorting becuase it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occured.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in PF_EndSort()). See PutOut() and FlushOut().

This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of PF_Processor(). (TU 30 Jun 2011)

Definition at line 864 of file parallel.c.

4.39.4.12 PF_Deferred()

```
WORD PF_Deferred (

WORD * term,

WORD level )
```

Replaces Deferred() on the slaves.

Parameters

term	the term that must be multiplied by the contents of the current bracket.
level	the compiler level.

Returns

0 if OK, nonzero on error.

Definition at line 1208 of file parallel.c.

4.39.4.13 PF_Processor()

Replaces parts of Processor() on the masters and slaves. On the master PF_Processor() is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls Generator() for all the terms that this process gets, but PF_GetTerm() gets terms from the master (not directly from infile).

Parameters

e	The pointer to the current expression.
i	The index for the current expression.
LastExpression	The flag indicating whether it is the last expression.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file parallel.c.

4.39.4.14 PF_Init()

```
int PF_Init (
                int * argc,
                char *** argv )
```

All the library independent stuff. PF_LibInit() should do all library dependent initializations.

Parameters

argc	pointer to the number of arguments.
argv	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 1953 of file parallel.c.

4.39.4.15 PF_Terminate()

Performs the finalization of ParFORM. To be called by Terminate().

Parameters

```
error an error code.
```

Returns

0 if OK, nonzero on error.

Definition at line 2047 of file parallel.c.

References PF_LibTerminate().

4.39.4.16 PF_GetSlaveTimes()

```
LONG PF_GetSlaveTimes ( void )
```

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2063 of file parallel.c.

4.39.4.17 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber ( \label{eq:long_problem} \mbox{LONG } x \mbox{ )}
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x the number to be broadcast (set on the master).

Returns

the synchronised result.

Definition at line 2083 of file parallel.c.

4.39.4.18 PF_BroadcastBuffer()

Broadcasts a buffer from the master to all the slaves.

Parameters

in,out	buffer	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the
		length is greater than 0. The caller must free it.
in,out	length	on the master, the length of the buffer to be broadcast. On the slaves, it receives the
		length of transfered buffer. The actual transfer occurs only if the length is greater than 0.

Definition at line 2110 of file parallel.c.

4.39.4.19 PF_BroadcastString()

```
int PF_BroadcastString ( {\tt UBYTE} \ * \ str \ )
```

Broadcasts a string from the master to all slaves.

Parameters

in,out	str	The pointer to a null-terminated string.
--------	-----	--

Returns

0 if OK, nonzero on error.

Definition at line 2152 of file parallel.c.

4.39.4.20 PF_BroadcastPreDollar()

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like #\$a=g; where g is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in *dbuffer of the size is *newsize (in number of WORDs), +1 for trailing zero. For slave newsize and numterms are output parameters.

Parameters

in,out	dbuffer	the buffer for a dollar variable.
in,out	newsize	the size of the dollar variable in WORDs.
in,out	numterms	the number of terms in the dollar variable.

Returns

0 if OK, nonzero on error.

Definition at line 2207 of file parallel.c.

4.39.4.21 PF_CollectModifiedDollars()

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot ← Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode.

Returns

0 if OK, nonzero on error.

Definition at line 2495 of file parallel.c.

4.39.4.22 PF_BroadcastModifiedDollars()

Broadcasts modified dollar variables on the master to the all slaves.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot ← Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode. In either cases, we need to broadcast them.

Returns

0 if OK, nonzero on error.

Definition at line 2774 of file parallel.c.

4.39.4.23 PF_BroadcastRedefinedPreVars()

Broadcasts preprocessor variables, which were changed by the Redefine statements in the current module, from the master to the all slaves.

The potentially redefined preprocessor variables are given in AC.pfirstnum, and the number of them is given by AC.numpfirstnum. For an actually redefined variable, the corresponding value in AC.inputnumbers is non-negative.

Returns

0 if OK, nonzero on error.

Definition at line 2991 of file parallel.c.

4.39.4.24 PF_BroadcastCBuf()

Broadcasts a compiler buffer specified by bufnum from the master to the all slaves.

Parameters

Returns

0 if OK, nonzero on error.

Definition at line 3133 of file parallel.c.

4.39.4.25 PF_BroadcastExpFlags()

Broadcasts AR.expflags and several properties of each expression, e.g., e->vflags, from the master to all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3244 of file parallel.c.

4.39.4.26 PF_BroadcastExpr()

Broadcasts an expression from the master to the all slaves.

Parameters

е	The expression to be broadcast.
file	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line 3538 of file parallel.c.

4.39.4.27 PF_BroadcastRHS()

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3566 of file parallel.c.

4.39.4.28 PF_InParallelProcessor()

Processes expressions in the InParallel mode, i.e., dividing expressions marked by partodo over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3613 of file parallel.c.

4.39.4.29 PF_SendFile()

Sends a file to the process specified by to.

Parameters

to	the destination process number.
fd	the file to be sent.

Returns

the size of sent data in bytes, or -1 on error.

Definition at line 4210 of file parallel.c.

References PF_RawSend().

4.39.4.30 PF_RecvFile()

```
int PF_RecvFile (
          int from,
          FILE * fd )
```

Receives a file from the process specified by from.

Parameters

from	the source process number.
fd	the file to save the received data.

Returns

the size of received data in bytes, or -1 on error.

Definition at line 4248 of file parallel.c.

4.39.4.31 PF_MLock()

```
void PF_MLock (
     void )
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4329 of file parallel.c.

4.39.4.32 PF_MUnlock()

```
void PF_MUnlock (
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4345 of file parallel.c.

4.39.4.33 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
int handle,

UBYTE * buffer,

LONG size )
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(Error MessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

handle	a file handle that specifies the output.
buffer	a pointer to the source buffer containing the data to be written.
Gegn <u>e</u> raated by	PENEOSITZE of data to be written in bytes.

Returns

the actual size of data written to the output in bytes.

Definition at line 4374 of file parallel.c.

4.39.4.34 PF_FlushStdOutBuffer()

Explicitly Flushes the buffer for the standard output on the master, which is used if $PF_ENABLE_STDOUT_{\leftarrow}$ BUFFERING is defined.

Definition at line 4468 of file parallel.c.

4.39.4.35 PF_FreeErrorMessageBuffers()

```
void PF_FreeErrorMessageBuffers ( \mbox{void} \ \ \mbox{)}
```

Frees the buffers allocated for the synchronized output.

Currently, not used anywhere, but could be used in PF_Terminate().

Definition at line 4604 of file parallel.c.

References VectorFree.

4.40 parallel.h File Reference

4.40.1 Detailed Description

Header file with things relevant to ParForm.

4.40.2 Function Documentation

4.40.2.1 PF_ISendSbuf()

```
int PF_ISendSbuf (
          int to,
          int tag )
```

Nonblocking send operation. It sends everything from buff to fill of the active buffer. Depending on tag it also can do waiting for other sends to finish or set the active buffer to the next one.

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 261 of file mpi.c.

4.40.2.2 PF_Bcast()

```
int PF_Bcast (
     void * buffer,
     int count )
```

Broadcasts a message from the master to slaves.

Parameters

in,out	buffer	the starting address of buffer. The contents in this buffer on the master will be transferred
		to those on the slaves.
	count	the length of the buffer in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 440 of file mpi.c.

4.40.2.3 PF_RawSend()

```
int PF_RawSend (
    int dest,
    void * buf,
    LONG 1,
    int tag )
```

Sends / bytes from buf to dest. Returns 0 on success, or -1.

Parameters

dest	the destination process number.
buf	the send buffer.
1	the size of data in the send buffer in bytes.
tag	the message tag.

Generated by Doxygen

Returns

0 if OK, nonzero on error.

Definition at line 463 of file mpi.c.

4.40.2.4 PF_RawRecv()

```
LONG PF_RawRecv (
    int * src,
    void * buf,
    LONG thesize,
    int * tag )
```

Receives not more than thesize bytes from src, returns the actual number of received bytes, or -1 on failure.

Parameters

in,out	src	the source process number. In output, that of the actual received message.
out	buf	the receive buffer.
	thesize	the size of the receive buffer in bytes.
out	tag	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 484 of file mpi.c.

4.40.2.5 PF_PreparePack()

Prepares for the next pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 624 of file mpi.c.

4.40.2.6 PF_Pack()

Adds data into the pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 642 of file mpi.c.

4.40.2.7 PF_Unpack()

```
int PF_Unpack (
     void * buffer,
     size_t count,
     MPI_Datatype type )
```

Retrieves the next data in the pack buffer.

Parameters

out	buffer	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 671 of file mpi.c.

4.40.2.8 PF_PackString()

Packs a string str into the packed buffer PF_packbuf, including the trailing zero.

The first element (PF_INT) is the length of the packed portion of the string. If the string does not fit to the buffer PF ← _packbuf, the function packs only the initial portion. It returns the number of packed bytes, so if (str[length-1]=='\0') then the whole string fits to the buffer, if not, then the rest (str+length) bust be packed and send again. On error, the function returns the negative error code.

One exception: the string "\0!\0" is used as an image of the NULL, so all 3 characters will be packed.

Parameters

```
str a string to be packed.
```

Returns

the number of packed bytes, or a negative value on failure.

Definition at line 706 of file mpi.c.

4.40.2.9 PF_UnpackString()

```
int PF_UnpackString ( {\tt UBYTE} \ * \ str \ )
```

Unpacks a string to str from the packed buffer PF_packbuf, including the trailing zero.

It returns the number of unpacked bytes, so if (str[length-1]=='\0') then the whole string was unpacked, if not, then the rest must be appended to (str+length). On error, the function returns the negative error code.

Parameters

out	str	the buffer to store the unpacked string
-----	-----	---

Returns

the number of unpacked bytes, or a negative value on failure.

Definition at line 774 of file mpi.c.

4.40.2.10 PF_Send()

Sends the contents in the pack buffer to the process specified by to.

Example:

```
if ( PF.me == SRC ) {
    PF_PreparePack();
    // Packing operations here...
    PF_Send(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_Receive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
```

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 822 of file mpi.c.

4.40.2.11 PF_Receive()

```
int PF_Receive (
    int src,
    int tag,
    int * psrc,
    int * ptag )
```

Receives data into the pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_Send().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	psrc	the actual source process number of received message.
out	ptag	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 848 of file mpi.c.

4.40.2.12 PF_Broadcast()

```
int PF_Broadcast (
     void )
```

Broadcasts the contents in the pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PreparePack();
    // Packing operations here...
}
PF_Broadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
```

Returns

0 if OK, nonzero on error.

Definition at line 883 of file mpi.c.

4.40.2.13 PF_PrepareLongSinglePack()

Prepares for the next long-single-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1451 of file mpi.c.

4.40.2.14 PF_LongSinglePack()

Adds data into the "long single" pack buffer.

Parameters

buf	fer	the pointer to the buffer storing the data to be packed.	
COL	ınt	the number of elements in the buffer.	
typ	e	the data type of elements in the buffer.	

Returns

0 if OK, nonzero on error.

Definition at line 1469 of file mpi.c.

4.40.2.15 PF_LongSingleUnpack()

```
size_t count,
MPI_Datatype type )
```

Retrieves the next data in the "long single" pack buffer.

Parameters

out	buffer	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1503 of file mpi.c.

4.40.2.16 PF_LongSingleSend()

```
int PF_LongSingleSend (  \qquad \qquad \text{int $to$,} \\ \qquad \qquad \text{int $tag$ )}
```

Sends the contents in the "long single" pack buffer to the process specified by to.

Example:

```
if ( PF.me == SRC ) {
    PF_PrepareLongSinglePack();
    // Packing operations here...
    PF_LongSingleSend(DEST, TAG);
}
else if ( PF.me == DEST ) {
    PF_LongSingleReceive(SRC, TAG, &actual_src, &actual_tag);
    // Unpacking operations here...
}
```

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file mpi.c.

4.40.2.17 PF_LongSingleReceive()

```
int PF_LongSingleReceive (
    int src,
    int tag,
    int * psrc,
    int * ptag )
```

Receives data into the "long single" pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_LongSingleSend().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	psrc	the actual source process number of received message.
out	ptag	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1583 of file mpi.c.

4.40.2.18 PF_PrepareLongMultiPack()

Prepares for the next long-multi-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1643 of file mpi.c.

4.40.2.19 PF_LongMultiPackImpl()

Adds data into the "long multi" pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
eSize	the byte size of each element of data.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 1662 of file mpi.c.

4.40.2.20 PF_LongMultiUnpackImpl()

```
int PF_LongMultiUnpackImpl (
    void * buffer,
    size_t count,
    size_t eSize,
    MPI_Datatype type )
```

Retrieves the next data in the "long multi" pack buffer.

Parameters

out.	buffer	the pointer to the buffer to store the unpacked data.
oue	Daner	•
	count	the number of elements of data to be received.
	eSize	the byte size of each element of data.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1721 of file mpi.c.

4.40.2.21 PF_LongMultiBroadcast()

Broadcasts the contents in the "long multi" pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
    PF_PrepareLongMultiPack();
    // Packing operations here...
}
PF_LongMultiBroadcast();
if ( PF.me != MASTER ) {
    // Unpacking operations here...
```

Returns

0 if OK, nonzero on error.

Definition at line 1807 of file mpi.c.

4.40.2.22 PF_EndSort()

```
int PF_EndSort (
     void )
```

Finishes a master sorting with collecting terms from slaves. Called by EndSort().

If this is not the masterprocess, just initialize the sendbuffers and return 0, else PF_EndSort() sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' (PF_GetLoser()) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if EndSort() still must perform a regular sorting becuase it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occured.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in PF_EndSort()). See PutOut() and FlushOut().

This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of PF_Processor(). (TU 30 Jun 2011)

Definition at line 864 of file parallel.c.

4.40.2.23 PF_Deferred()

```
WORD PF_Deferred ( WORD * term, WORD level )
```

Replaces Deferred() on the slaves.

Parameters

term	the term that must be multiplied by the contents of the current bracket.
level	the compiler level.

Returns

0 if OK, nonzero on error.

Definition at line 1208 of file parallel.c.

4.40.2.24 PF_Processor()

Replaces parts of Processor() on the masters and slaves. On the master PF_Processor() is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls Generator() for all the terms that this process gets, but PF_GetTerm() gets terms from the master (not directly from infile).

Parameters

е	The pointer to the current expression.
i	The index for the current expression.
LastExpression	The flag indicating whether it is the last expression.

Returns

0 if OK, nonzero on error.

Definition at line 1540 of file parallel.c.

4.40.2.25 PF_Init()

```
int PF_Init (
                int * argc,
                char *** argv )
```

All the library independent stuff. PF_LibInit() should do all library dependent initializations.

Parameters

argc	pointer to the number of arguments.
argv	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 1953 of file parallel.c.

4.40.2.26 PF_Terminate()

Performs the finalization of ParFORM. To be called by Terminate().

Parameters

```
error an error code.
```

Returns

0 if OK, nonzero on error.

Definition at line 2047 of file parallel.c.

References PF_LibTerminate().

4.40.2.27 PF_GetSlaveTimes()

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2063 of file parallel.c.

4.40.2.28 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber (  \label{eq:long_problem} \mbox{LONG } x \mbox{ )}
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x the number to be broadcast (set on the master).

Returns

the synchronised result.

Definition at line 2083 of file parallel.c.

4.40.2.29 PF_BroadcastBuffer()

Broadcasts a buffer from the master to all the slaves.

Parameters

in,out	buffer	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the length is greater than 0. The caller must free it.	
in,out	length	on the master, the length of the buffer to be broadcast. On the slaves, it receives the length of transfered buffer. The actual transfer occurs only if the length is greater than 0.	

Definition at line 2110 of file parallel.c.

4.40.2.30 PF_BroadcastString()

```
int PF_BroadcastString ( {\tt UBYTE} \ * \ str \ )
```

Broadcasts a string from the master to all slaves.

Parameters

in,out	str	The pointer to a null-terminated string.
--------	-----	--

Returns

0 if OK, nonzero on error.

Definition at line 2152 of file parallel.c.

4.40.2.31 PF_BroadcastPreDollar()

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like #\$a=g; where g is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in *dbuffer of the size is *newsize (in number of WORDs), +1 for trailing zero. For slave newsize and numterms are output parameters.

Parameters

in,out	dbuffer	the buffer for a dollar variable.
in,out	newsize	the size of the dollar variable in WORDs.
in,out	numterms	the number of terms in the dollar variable.

Returns

0 if OK, nonzero on error.

Definition at line 2207 of file parallel.c.

4.40.2.32 PF_CollectModifiedDollars()

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot ← Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode.

Returns

0 if OK, nonzero on error.

Definition at line 2495 of file parallel.c.

4.40.2.33 PF_BroadcastModifiedDollars()

Broadcasts modified dollar variables on the master to the all slaves.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot ← Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode. In either cases, we need to broadcast them.

Returns

0 if OK, nonzero on error.

Definition at line 2774 of file parallel.c.

4.40.2.34 PF_BroadcastRedefinedPreVars()

Broadcasts preprocessor variables, which were changed by the Redefine statements in the current module, from the master to the all slaves.

The potentially redefined preprocessor variables are given in AC.pfirstnum, and the number of them is given by AC.numpfirstnum. For an actually redefined variable, the corresponding value in AC.inputnumbers is non-negative.

Returns

0 if OK, nonzero on error.

Definition at line 2991 of file parallel.c.

4.40.2.35 PF_BroadcastCBuf()

Broadcasts a compiler buffer specified by bufnum from the master to the all slaves.

Parameters

bufnum	The index of the compiler buffer to be broadcast.
--------	---

Returns

0 if OK, nonzero on error.

Definition at line 3133 of file parallel.c.

4.40.2.36 PF_BroadcastExpFlags()

Broadcasts AR.expflags and several properties of each expression, e.g., e->vflags, from the master to all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3244 of file parallel.c.

4.40.2.37 PF_BroadcastExpr()

Broadcasts an expression from the master to the all slaves.

Parameters

е	The expression to be broadcast.
file	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line 3538 of file parallel.c.

4.40.2.38 PF_BroadcastRHS()

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3566 of file parallel.c.

4.40.2.39 PF_InParallelProcessor()

Processes expressions in the InParallel mode, i.e., dividing expressions marked by partodo over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3613 of file parallel.c.

4.40.2.40 PF_SendFile()

```
int PF_SendFile (
          int to,
          FILE * fd )
```

Sends a file to the process specified by to.

Parameters

	to	the destination process number.
ĺ	fd	the file to be sent.

Returns

the size of sent data in bytes, or -1 on error.

Definition at line 4210 of file parallel.c.

References PF_RawSend().

4.40.2.41 PF_RecvFile()

```
int PF_RecvFile (
          int from,
          FILE * fd )
```

Receives a file from the process specified by from.

Parameters

from	the source process number.
fd	the file to save the received data.

Returns

the size of received data in bytes, or -1 on error.

Definition at line 4248 of file parallel.c.

4.40.2.42 PF_MLock()

```
void PF_MLock (
     void )
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4329 of file parallel.c.

4.40.2.43 PF_MUnlock()

```
void PF_MUnlock (
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4345 of file parallel.c.

4.40.2.44 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
int handle,

UBYTE * buffer,

LONG size )
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(Error MessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

handle	a file handle that specifies the output.	
buffer	a pointer to the source buffer containing the data to be written.	
size	the size of data to be written in bytes.	1

Returns

the actual size of data written to the output in bytes.

Definition at line 4374 of file parallel.c.

4.40.2.45 PF_FlushStdOutBuffer()

Explicitly Flushes the buffer for the standard output on the master, which is used if PF_ENABLE_STDOUT_

BUFFERING is defined.

Definition at line 4468 of file parallel.c.

4.41 pattern.c File Reference

4.41.1 Detailed Description

Top level pattern matching routines. More pattern matching is found in findpat.c, function.c, symmetr.c and smart.c. The last three files contain the matching inside functions. The file pattern.c contains also the very important routine Substitute. All regular pattern matching is just the finding of the pattern and indicating what are the wildcards etc. The routine Substitute does the actual removal of the pattern and replaces it by a subterm of the type SUBEXPRES-SION.

4.41.2 Macro Definition Documentation

4.41.2.1 PutInBuffers

```
#define PutInBuffers(
                   pow )
Value:
    AddRHS (AT.ebufnum, 1); \
     *out++ = SUBEXPRESSION; \
     *out++ = SUBEXPSIZE; \
     *out++ = C->numrhs; \
    *out++ = pow; \
*out++ = AT.ebufnum; \
    FILLSUB(out) \
     r = AT.pWorkSpace[rhs+i]; \
    if ( *r > 0 ) { \
         oldinr = r[*r]; r[*r] = 0; \
          \begin{tabular}{ll} AddNtoC(AT.ebufnum, (*r+1-ARGHEAD), (r+ARGHEAD), 14); \\ \end{tabular} \label{table}
         r[*r] = oldinr; \setminus
    else { \
         ToGeneral (r, buffer, 1); \
         buffer[buffer[0]] = 0;
         AddNtoC(AT.ebufnum, buffer[0]+1, buffer, 15); \
```

Definition at line 2193 of file pattern.c.

4.41.3 Function Documentation

4.41.3.1 TestMatch()

```
WORD TestMatch (

PHEAD WORD * term,

WORD * level )
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in *AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV): We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

Functions

- bool gcd_heuristic_possible (const poly &a)
- const poly gcd_linear_helper (const poly &a, const poly &b)

4.43.1 Detailed Description

Contains the routines for calculating greatest commons divisors of multivariate polynomials

4.43.2 Function Documentation

4.43.2.1 gcd heuristic possible()

Heuristic greatest common divisor of multivariate polynomials

4.43.3 Description

Checks whether the heuristic seems possible by estimating MAX_{terms} (coeff ^ PROD_{i=1..#vars} (pow_i+1)) and comparing this with GCD_HEURISTIC_MAX_DIGITS.

4.43.4 Notes

• For small polynomials, this consumes time and never triggers.

Variables

const int POLYWRAP_DENOMPOWER_INCREASE_FACTOR = 2

4.44.1 Detailed Description

Contains methods to call the polynomial methods (written in C++) from the rest of Form (written in C). These include polynomial gcd computation, factorization and polyratfuns.

4.44.2 Function Documentation

4.44.2.1 poly_determine_modulus()

```
WORD poly_determine_modulus (
          PHEAD bool multi_error,
          bool is_fun_arg,
          string message )
```

Modulus for polynomial algebra

4.44.3 Description

This method determines whether polynomial algebra is done with a modulus or not. This depends on AC.ncmod. If only_funargs is set it also depends on (AC.modmode & ALSOFUNARGS).

The program terminates if the feature is not implemented. Polynomial algebra modulo M > WORDSIZE in not implemented. If multi_error is set, multivariate algebra mod M is not implemented.

4.44.4 Notes

• If AC.ncmod>0 and only_funargs=true and AC.modmode&ALSOFUNARGS=false, AN.ncmod is set to zero, for otherwise RaisPow calculates mod M.

Definition at line 79 of file polywrap.cc.

4.44.4.1 poly_gcd()

Polynomial gcd

4.44.5 Description

This method calculates the greatest common divisor of two polynomials, given by two zero-terminated Form-style term lists.

4.44.6 Notes

- · The result is written at newly allocated memory
- · Called from ratio.c
- · Calls polygcd::gcd

Definition at line 124 of file polywrap.cc.

4.44.6.1 poly_ratfun_read()

Read a PolyRatFun

4.44.7 Description

This method reads a polyratfun starting at the pointer a. The resulting numerator and denominator are written in num and den. If MUSTCLEANPRF, the result is normalized.

4.44.8 Notes

· Calls polygcd::gcd

Definition at line 471 of file polywrap.cc.

4.44.8.1 poly_sort()

Sort the polynomial terms

4.44.9 Description

Sorts the terms of a polynomial in Form poly(rat)fun order, i.e. lexicographical order with highest degree first.

4.44.10 Notes

· Uses Form sort routines with custom compare

Definition at line 557 of file polywrap.cc.

4.44.10.1 poly_ratfun_add()

Addition of PolyRatFuns

4.44.11 Description

This method gets two pointers to polyratfuns with up to two arguments each and calculates the sum.

4.44.12 Notes

- · The result is written at the workpointer
- Called from sort.c and threads.c
- Calls poly::operators and polygcd::gcd

Definition at line 600 of file polywrap.cc.

4.44.12.1 poly_ratfun_normalize()

```
int poly_ratfun_normalize ( {\tt PHEAD\ WORD\ *\ term\ )}
```

Multiplication/normalization of PolyRatFuns

4.44.13 Description

This method seaches a term for multiple polyratfuns and multiplies their contents. The result is properly normalized. Normalization also works for terms with a single polyratfun.

4.44.14 Notes

- · The result overwrites the original term
- · Called from proces.c
- · Calls poly::operators and polygcd::gcd

Definition at line 719 of file polywrap.cc.

4.44.14.1 poly_factorize()

Factorization of function arguments / dollars

4.44.15 Description

This method factorizes a Form style argument or zero-terminated term list.

4.44.16 Notes

- Called from poly_factorize_{argument,dollar}
- Calls polyfact::factorize

Definition at line 922 of file polywrap.cc.

4.44.16.1 poly_factorize_argument()

Factorization of function arguments

4.44.17 Description

This method factorizes the Form-style argument argin.

4.44.18 Notes

- · The result is written at argout
- Called from argument.c
- · Calls poly_factorize

Definition at line 1047 of file polywrap.cc.

4.44.18.1 poly_factorize_dollar()

Factorization of dollar variables

4.44.19 Description

This method factorizes a dollar variable.

4.44.20 Notes

- The result is written at newly allocated memory.
- Called from dollar.c
- · Calls poly_factorize

Definition at line 1074 of file polywrap.cc.

4.44.20.1 poly_factorize_expression()

```
int poly_factorize_expression ( $\tt EXPRESSIONS \ expr \ )
```

Factorization of expressions

4.44.21 Description

This method factorizes an expression.

4.44.22 Notes

- · The result overwrites the input expression
- · Called from proces.c
- · Calls polyfact::factorize

Definition at line 1100 of file polywrap.cc.

4.46.1 Detailed Description

This is the preprocessor and all its routines.

4.46.2 Function Documentation

4.46.2.1 PutPreVar()

Inserts/Updates a preprocessor variable in the name administration.

Parameters

name	Character string with the variable name.
value	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a?
args	Character string with possible arguments.
mode	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

Definition at line 713 of file pre.c.

4.46.2.2 TheDefine()

```
int TheDefine ( \label{eq:define} \mbox{UBYTE * $s$,} \\ \mbox{int $mode$ )}
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

s	Pointer to the character string following the preprocessor command.
mode	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit
	set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 2019 of file pre.c.

4.46.2.3 DoPreAppendPath()

```
int DoPreAppendPath ( {\tt UBYTE} \ * \ s \ )
```

Appends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #appendpath < path>

Definition at line 7105 of file pre.c.

4.46.2.4 DoPrePrependPath()

```
int DoPrePrependPath ( {\tt UBYTE} \ * \ s \ )
```

Prepends the given path (absolute or relative to the current file directory) to the FORM path.

Syntax: #prependpath <path>

Definition at line 7122 of file pre.c.

4.47 proces.c File Reference

```
#include "form3.h"
```

Variables

• WORD printscratch [2]

4.47.1 Detailed Description

Contains the central terms processor routines. This is the core of the virtual machine. All other files are to help these routines.

4.47.2 Macro Definition Documentation

4.47.2.1 DONE

```
#define DONE(
     x ) { retvalue = x; goto Done; }
```

TestSub hunts for subexpression pointers. If one is found its power is given in AN.TeSuOut. and the returnvalue is 'expressionnumber'. If the expression number is negative it is an expression on disk.

In addition this routine tries to locate subexpression pointers in functions. It also notices that action must be taken with any of the special functions.

Parameters

	The term in which TestSub hunts for potential action
level	The number of the 'level' in the compiler buffer.

Returns

The number of the (sub)expression that was encountered.

Other values that are returned are in AN.TeSuOut, AR.TePos, AT.TMbuff, AN.TeInFun, AN.Frozen, AT.TMaddr

The level in the compiler buffer is more or less the number of the statement in the module. Hence it refers to the element in the lhs array.

This routine is one of the most important routines in FORM.

Definition at line 682 of file proces.c.

4.47.3 Function Documentation

4.47.3.1 Processor()

```
WORD Processor ( VOID )
```

This is the central processor. It accepts a stream of Expressions which is accessed by calls to GetTerm. The expressions reside either in AR.infile or AR.hidefile The definitions of an expression are seen as an id-statement, so the primary Expressions should be written to the system of scratch files as single terms with an expression pointer. Each expression is terminated with a zero and the whole is terminated by two zeroes.

The routine DoExecute should determine whether results are to be printed, should revert the scratch I/O directions etc. In principle it is DoExecute that calls Processor.

Returns

if everything OK: 0. Otherwise error. The preprocessor may continue with compilation though. Really fatal errors should return on the spot by calling Terminate.

Definition at line 64 of file proces.c.

4.47.3.2 InFunction()

```
WORD InFunction (

PHEAD WORD * term,

WORD * termout )
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

term	The input term
termout	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

Special attention should be given to nested functions!

Definition at line 2174 of file proces.c.

4.47.3.3 InsertTerm()

```
WORD InsertTerm (

PHEAD WORD * term,

WORD replac,

WORD extractbuff,

WORD * position,

WORD * termout,

WORD tepos )
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

term	the input term
replac	number of the subexpression pointer to replace
extractbuff	number of the compiler buffer replac refers to
position	position from where to take the term in the compiler buffer
termout	the output term
tepos	offset in term where the subexpression is.

Returns

Normal conventions (OK = 0).

Definition at line 2720 of file proces.c.

4.47.3.4 PasteFile()

```
LONG PasteFile ( {\tt PHEAD\ WORD\ \it number,}
```

```
WORD * accum,

POSITION * position,

WORD ** accfill,

RENUMBER renumber,

WORD * freeze,

WORD nexpr)
```

Gets a term from stored expression expr and puts it in the accumulator at position number. It returns the length of the term that came from file.

Parameters

number	number of partial terms to skip in accum
accum	the accumulator
position	file position from where to get the stored term
accfill	returns tail position in accum
renumber	the renumber struct for the variables in the stored expression
freeze	information about if we need only the contents of a bracket
nexpr	the number of the stored expression

Returns

Normal conventions (OK = 0).

Definition at line 2856 of file proces.c.

4.47.3.5 PasteTerm()

```
WORD* PasteTerm (

PHEAD WORD number,

WORD * accum,

WORD * position,

WORD times,

WORD divby )
```

Puts the term at position in the accumulator accum at position 'number+1'. if times > 0 the coefficient of this term is multiplied by times/divby.

Parameters

number	The number of term fragments in accum that should be skipped
accum	The accumulator of term fragments
position	A position in (typically) a compiler buffer from where a (piece of a) term comes.
times	Multiply the result by this
divby	Divide the result by this.

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new

expression. The factors times and divby keep track of the binomial coefficient. Once this is complete, the routine FiniTerm will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line 2978 of file proces.c.

4.47.3.6 FiniTerm()

```
WORD FiniTerm (

PHEAD WORD * term,

WORD * accum,

WORD * termout,

WORD number,

WORD tepos)
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

term	the input term with the (sub)expression subterm
accum	the accumulator with the term fragments
termout	the location where the output should be written
number	the number of term fragments in the accumulator
tepos	the position of the subterm in term to be replaced

Definition at line 3043 of file proces.c.

4.47.3.7 Generator()

```
WORD Generator (

PHEAD WORD * term,

WORD level )
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

	term	the input term. may be overwritten
Ī	level	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this

is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

Definition at line 3242 of file proces.c.

4.47.3.8 DoOnePow()

```
WORD DoOnePow (

PHEAD WORD * term,

WORD power,

WORD nexp,

WORD * accum,

WORD * aa,

WORD level,

WORD * freeze )
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commutating properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

term	is the term we are adding to.
	-
power	is the power of the expression that we need.
nexp	is the number of the expression.
accum	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm
aa	points to the start of the entire accumulator. In *aa we store the number of term fragments that are in
	the accumulator.
level	is the current depth in the tree of statements. It is needed to continue to the next
	operation/substitution with each generated term
freeze	is the pointer to the bracket information that should be matched.

Definition at line 4589 of file proces.c.

4.47.3.9 Deferred()

```
WORD Deferred (

PHEAD WORD * term,

WORD level )
```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

term	The term that must be multiplied by the contents of the current bracket
level	The compiler level. This is needed because after multiplying term by term we call Generator again.

Definition at line 4810 of file proces.c.

4.47.3.10 PrepPoly()

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

The parameter par tells whether we are at groundlevel or inside a function or dollar variable.

Definition at line 4938 of file proces.c.

4.47.3.11 PolyFunMul()

```
WORD PolyFunMul ( {\tt PHEAD\ WORD\ *\ term\ )}
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file polywrap.cc The new result is written over the old result.

Parameters

term	It contains the input term and later the output.
------	--

Returns

Normal conventions (OK = 0).

Definition at line 5326 of file proces.c.

4.48 ratio.c File Reference

4.48.1 Detailed Description

A variety of routines: The ratio command for partial fractioning (rather old. Schoonschip inheritance) The sum routines.

4.48 ratio.c File Reference 361

4.48.2 Function Documentation

4.48.2.1 TakeContent()

```
WORD* TakeContent (

PHEAD WORD * in,

WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

Definition at line 1376 of file ratio.c.

4.48.2.2 TakeSymbolContent()

```
WORD* TakeSymbolContent (
          PHEAD WORD * in,
          WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. Output: term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

Definition at line 2434 of file ratio.c.

4.49.1 Detailed Description

This file contains the numerical routines. The arithmetic in FORM is normally over the rational numbers. Hence there are routines for dealing with integers and with rational of 'arbitrary precision' (within limits) There are also routines for that calculus modulus an integer. In addition there are the routines for factorials and bernoulli numbers. The random number function is currently only for internal purposes.

4.49.2 Function Documentation

4.49.2.1 RaisPowCached()

```
VOID RaisPowCached (

PHEAD WORD x,

WORD n,

UWORD ** c,

WORD * nc)
```

Computes power x^n and caches the value

4.49.3 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.49.4 Notes

· Caching is done in AT.small_power[]. This array is extended if necessary.

Definition at line 1296 of file reken.c.

Referenced by poly::divmod_univar(), and poly::mul_heap().

4.49.4.1 NormalModulus()

```
int NormalModulus ( {\tt UWORD} \ * \ a \text{,} {\tt WORD} \ * \ na \ )
```

Brings a modular representation in the range -p/2 to +p/2 The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1403 of file reken.c.

4.49.4.2 MakeInverses()

Makes a table of inverses in modular calculus The modulus is in AC.cmod and AC.ncmod One should notice that the table of inverses can only be made if the modulus fits inside a single FORM word. Otherwise the table lookup becomes too difficult and the table too long.

Definition at line 1440 of file reken.c.

4.49.4.3 GetModInverses()

Input m1 and m2, which are relative prime. determines a*m1+b*m2 = 1 (and 1 is the gcd of m1 and m2) then $a*m1 = 1 \mod m2$ and hence im1 = a. and $b*m2 = 1 \mod m1$ and hence im2 = b. Set m1 = 0*m1+1*m2 = a1*m1+b1*m2 m2 = 1*m1+0*m2 = a2*m1+b2*m2 If everything is OK, the return value is zero

Definition at line 1476 of file reken.c.

4.49.4.4 CompCoef()

```
WORD CompCoef ( WORD * term1, \\ WORD * term2 ) Routine takes a1 mod m1 and a2 mod m2 and returns a mod m1*m2 with a mod m1 = a1 and a mod m2 = a2
```

Chinese remainder: a%(m1*m2) = q1*m1+a1 a%(m1*m2) = q2*m2+a2 Compute n1 such that (n1*m1)m2 is one Compute n2 such that (n2*m2)m1 is one Then (a1*n2*m2+a2*n1*m1)%(m1*m2) is a%(m1*m2)

Definition at line 3047 of file reken.c.

4.49.4.5 NextPrime()

```
WORD NextPrime ( {\tt PHEAD\ WORD\ \it num\ )}
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

Definition at line 3664 of file reken.c.

4.54.1 Detailed Description

Contains the sort routines. We distinguish levels of sorting. The ground level is the sorting of terms in an expression. When a term has functions, the arguments can contain terms that need sorting, which this then done by raising the level. This can happen recursively. NewSort and EndSort automatically raise and lower the level. Because the ground level does some special things, sometimes we have to raise immediately to the second level skipping the ground level.

Special routines for the parallel sorting are in the file threads.c Also the sorting of terms in polynomials is special but most of that is controlled by changing the address of the compare routine. Other routines relevant for adding rational polynomials are in the file polynito.c

4.54.2 Function Documentation

4.54.2.1 WriteStats()

Writes the statistics.

Parameters

plspace	The size in bytes currently occupied
par	par = 0 after a splitmerge. par = 1 after merge to sortfile. par = 2 after the sort

current expression is to be found in AR.CurExpr. terms are in S->TermsLeft. S->GenTerms.

Definition at line 93 of file sort.c.

4.54.2.2 NewSort()

```
WORD NewSort ( PHEAD0 )
```

Starts a new sort. At the lowest level this is a 'main sort' with the struct according to the parameters in S0. At higher levels this is a sort for functions, subroutines or dollars. We prepare the arrays and structs.

Returns

Regular convention (OK -> 0)

Definition at line 592 of file sort.c.

4.54.2.3 EndSort()

Finishes a sort. At AR.sLevel == 0 the output is to the regular output stream. When AR.sLevel > 0, the parameter par determines the actual output. The AR.sLevel will be popped. All ongoing stages are finished and if the sortfile is open it is closed. The statistics are printed when AR.sLevel == 0 par == 0 Output to the buffer. par == 1 Sort for function arguments. The output will be copied into the buffer. It is assumed that this is in the WorkSpace. par == 2 Sort for \$-variable. We return the address of the buffer that contains the output in buffer (treated like WORD **). We first catch the output in a file (unless we can intercept things after the small buffer has been sorted) Then we read from the file into a buffer. Only when par == 0 data compression can be attempted at AT.SS==AT.SO.

Parameters

buffer	buffer for output when needed
par	See above

Returns

If negative: error. If positive: number of words in output.

4.54 sort.c File Reference 371

Definition at line 682 of file sort.c.

4.54.2.4 PutIn()

Reads a new patch from position in file handle. It is put at buffer, anything after take is moved forward. This would be part of a term that hasn't been used yet. Because of this there should be some space before the start of the buffer

Parameters

file	The file system from which to read
position	The position from which to read
buffer	The buffer into which to read
take	The unused tail should be moved before the buffer
npat	The number of the patch. Is needed if the information was compressed with gzip, because each
	patch has its own independent gzip encoding.

Definition at line 1259 of file sort.c.

4.54.2.5 Sflush()

Puts the contents of a buffer to output Only to be used when there is a single patch in the large buffer.

Parameters

```
fi The filesystem (or its cache) to which the patch should be written
```

Definition at line 1319 of file sort.c.

4.54.2.6 PutOut()

```
WORD PutOut ( \label{eq:phead_word} {\tt PHEAD_WORD\ *\ term,}
```

```
POSITION * position,
FILEHANDLE * fi,
WORD ncomp )
```

Routine writes one term to file handle at position. It returns the new value of the position.

NOTE: For 'final output' we may have to index the brackets. See the struct BRACKETINDEX. We should maintain: 1: a list with brackets array with the brackets 2: a list of objects of type BRACKETINDEX. It contains array with either pointers or offsets to the list of brackets. starting positions in the file. The index may be tied to a maximum size. In that case we may have to prune the list occasionally.

Parameters

term	The term to be written
position	The position in the file. Afterwards it is updated
fi	The file (or its cache) to which should be written
псотр	Information about what type of compression should be used

Definition at line 1405 of file sort.c.

4.54.2.7 FlushOut()

Completes output to an output file and writes the trailing zero.

Parameters

position	The position in the file after writing
fi	The file (or its cache)
compr	Indicates whether there should be compression with gzip.

Returns

Regular conventions (OK -> 0).

Definition at line 1767 of file sort.c.

4.54.2.8 AddCoef()

```
WORD AddCoef (

PHEAD WORD ** ps1,

WORD ** ps2 )
```

4.54 sort.c File Reference 373

Adds the coefficients of the terms *ps1 and *ps2. The problem comes when there is not enough space for a new longer coefficient. First a local solution is tried. If this is not succesfull we need to move terms around. The possibility of a garbage collection should not be ignored, as avoiding this costs very much extra space which is nearly wasted otherwise.

If the return value is zero the terms cancelled.

The resulting term is left in *ps1.

Definition at line 1981 of file sort.c.

4.54.2.9 AddPoly()

```
WORD AddPoly (

PHEAD WORD ** ps1,

WORD ** ps2)
```

Routine should be called when S->PolyWise != 0. It points then to the position of AR.PolyFun in both terms.

We add the contents of the arguments of the two polynomials. Special attention has to be given to special arguments. We have to reserve a space equal to the size of one term + the size of the argument of the other. The addition has to be done in this routine because not all objects are reentrant.

Newer addition (12-nov-2007). The PolyFun can have two arguments. In that case S->PolyFlag is 2 and we have to call the routine for adding rational polynomials. We have to be rather careful what happens with: The location of the output The order of the terms in the arguments At first we allow only univariate polynomials in the PolyFun. This restriction will be lifted a.s.a.p.

Parameters

ps1	A pointer to the postion of the first term
ps2	A pointer to the postion of the second term

Returns

If zero the terms cancel. Otherwise the new term is in *ps1.

Definition at line 2110 of file sort.c.

4.54.2.10 AddArgs()

Adds the arguments of two occurrences of the PolyFun.

Parameters

s1	Pointer to the first occurrence.
s2	Pointer to the second occurrence.
m	Pointer to where the answer should be.

Definition at line 2272 of file sort.c.

4.54.2.11 Compare1()

```
WORD Compare1 (
          PHEAD WORD * term1,
          WORD * term2,
          WORD level )
```

Compares two terms. The answer is: 0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first. Some special precautions may be needed to keep the CompCoef routine from generating overflows, although this is very unlikely in subterms. This routine should not return an error condition.

Originally this routine was called Compare. With the treatment of special polynomials with terms that contain only symbols and the need for extreme speed for the polynomial routines we made a special compare routine and now we store the address of the current compare routine in AR.CompareRoutine and have a macro Compare which makes all existing code work properly and we can just replace the routine on a thread by thread basis (each thread has its own AR struct).

Parameters

term1	First input term
term2	Second input term
level	The sorting level (may influence on the result)

Returns

0 equal (with exception of the coefficient if level == 0.) >0 term1 comes first. <0 term2 comes first.

When there are floating point numbers active (float_ = FLOATFUN) the presence of one or more float_ functions is returned in AT.SortFloatMode: 0: no float_ 1: float_ in term1 only 2: float_ in term2 only 3: float_ in both terms

Definition at line 2565 of file sort.c.

4.54.2.12 CompareSymbols()

```
WORD CompareSymbols (

PHEAD WORD * term1,

WORD * term2,

WORD par )
```

4.54 sort.c File Reference 375

Compares the terms, based on the value of AN.polysortflag. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 The coefficients may differ. The terms contain only a single subterm of type SYMBOL. If AN.polysortflag = 0 it is a 'regular' compare. If AN.polysortflag = 1 the sum of the powers is more important par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 3029 of file sort.c.

4.54.2.13 CompareHSymbols()

```
WORD CompareHSymbols (

PHEAD WORD * term1,

WORD * term2,

WORD par )
```

Compares terms that can have only SYMBOL and HAAKJE subterms. If term1 < term2 the return value is -1 If term1 > term2 the return value is 1 If term1 = term2 the return value is 0 par is a dummy parameter to make the parameter field identical to that of Compare1 which is the regular compare routine in sort.c

Definition at line 3072 of file sort.c.

4.54.2.14 ComPress()

```
LONG ComPress (

WORD ** ss,

LONG * n )
```

Gets a list of pointers to terms and compresses the terms. In n it collects the number of terms and the return value of the function is the space that is occupied.

We have to pay some special attention to the compression of terms with a PolyFun. This PolyFun should occur only straight before the coefficient, so we can use the same trick as for the coefficient to sabotage compression of this object (Replace in the history the function pointer by zero. This is safe, because terms that would be identical otherwise would have been added).

Parameters

ss	Array of pointers to terms to be compressed.
n	Number of pointers in ss.

Returns

Total number of words needed for the compressed result.

Definition at line 3125 of file sort.c.

4.54.2.15 SplitMerge()

```
LONG SplitMerge (

PHEAD WORD ** Pointer,

LONG number )
```

Algorithm by J.A.M. Vermaseren (31-7-1988)

Note that AN.SplitScratch and AN.InScratch are used also in GarbHand

Merge sort in memory. The input is an array of pointers. Sorting is done recursively by dividing the array in two equal parts and calling SplitMerge for each. When the parts are small enough we can do the compare and take the appropriate action. An addition is that we look for 'runs'. Sequences that are already ordered. This happens a lot when there is very little action in a module. This made FORM faster by a few percent.

Parameters

Pointer	The array of pointers to the terms to be sorted.
number	The number of pointers in Pointer.

The terms are supposed to be sitting in the small buffer and there is supposed to be an extension to this buffer for when there are two terms that should be added and the result takes more space than each of the original terms. The notation guarantees that the result never needs more space than the sum of the spaces of the original terms.

Definition at line 3291 of file sort.c.

4.54.2.16 GarbHand()

```
VOID GarbHand (
```

Garbage collection that takes place when the small extension is full and we need to place more terms there. When this is the case there are many holes in the small buffer and the whole can be compactified. The major complication is the buffer for SplitMerge. There are to options for temporary memory: 1: find some buffer that has enough space (maybe in the large buffer). 2: allocate a buffer. Give it back afterwards of course. If the small extension is properly dimensioned this routine should be called very rarely. Most of the time it will be called when the polyfun or polyratfun is active.

Definition at line 3513 of file sort.c.

4.54.2.17 MergePatches()

```
WORD MergePatches ( \label{eq:word_par} \text{WORD } par \ )
```

The general merge routine. Can be used for the large buffer and the file merging. The array S->Patches tells where the patches start S->pStop tells where they end (has to be computed first). The end of a 'line to be merged' is indicated by a zero. If the end is reached without running into a zero or a term runs over the boundary of a patch it is a file merging operation and a new piece from the file is read in.

4.54 sort.c File Reference 377

Parameters

par

If par == 0 the sort is for file -> outputfile. If par == 1 the sort is for large buffer -> sortfile. If par == 2 the sort is for large buffer -> outputfile.

Definition at line 3628 of file sort.c.

4.54.2.18 StoreTerm()

```
WORD StoreTerm ( {\tt PHEAD\ WORD\ *\ term\ )}
```

The central routine to accept terms, store them and keep things at least partially sorted. A call to EndSort will then complete storing and sorting.

Parameters

term The term to be stored

Returns

Regular return conventions (OK -> 0)

Definition at line 4394 of file sort.c.

4.54.2.19 StageSort()

Prepares a stage 4 or higher sort. Stage 4 sorts occur when the sort file contains more patches than can be merged in one pass.

Definition at line 4514 of file sort.c.

4.54.2.20 SortWild()

```
WORD SortWild ( \label{eq:word word word word nw} \mbox{WORD } nw \mbox{ )}
```

Sorts the wildcard entries in the parameter w. Double entries are removed. Full space taken is nw words. Routine serves for the reading of wildcards in the compiler. The entries come in the format: (type,4,number,0) in which the zero is reserved for the future replacement of 'number'.

Parameters

W	buffer with wildcard entries.
nw	number of wildcard entries.

Returns

```
Normal conventions (OK -> 0)
```

Definition at line 4613 of file sort.c.

4.54.2.21 CleanUpSort()

```
void CleanUpSort (
          int num )
```

Partially or completely frees function sort buffers.

Definition at line 4705 of file sort.c.

4.54.2.22 LowerSortLevel()

Lowers the level in the sort system.

Definition at line 4788 of file sort.c.

4.55 spectator.c File Reference

4.57 store.c File Reference 381

4.57.1 Detailed Description

Contains all functions that deal with store-files and the system independent save-files.

4.57.2 Function Documentation

4.57.2.1 SetFileIndex()

```
WORD SetFileIndex ( VOID )
```

Reads the next file index and puts it into AR.StoreData.Index. TODO

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 2306 of file store.c.

4.57.2.2 TermRenumber()

```
WORD TermRenumber (

WORD * term,

RENUMBER renumber,

WORD nexpr )
```

!! WORD *memterm=term; static LONG ctrap=0; !!!

!! ctrap++; !!!

Definition at line 2413 of file store.c.

4.57.2.3 WriteStoreHeader()

```
WORD WriteStoreHeader ( \label{eq:word} \mbox{WORD } \mbox{\it handle} \mbox{\it )}
```

Writes header with information about system architecture and FORM revision to an open store file.

Called by SetFileIndex().

Parameters

handle spec	ifies open file to which header will be written
-------------	---

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 3957 of file store.c.

4.57.2.4 ReadSaveHeader()

```
WORD ReadSaveHeader ( VOID )
```

Reads the header in the save file and sets function pointers and flags according to the information found there. Must be called before any other ReadSave... function.

Currently works only for the exchange between 32bit and 64bit machines (WORD size must be 2 or 4 bytes)!

It is called by CoLoad().

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4050 of file store.c.

4.57.2.5 ReadSaveIndex()

```
WORD ReadSaveIndex ( FILEINDEX * fileind )
```

Reads a FILEINDEX from the open save file specified by AO.SaveData.Handle. Translations for adjusting endianness and data sizes are done if necessary.

Depends on the assumption that sizeof(FILEINDEX) is the same everywhere. If FILEINDEX or INDEXENTRY change, then this functions has to be adjusted.

Called by CoLoad() and FindInIndex().

Parameters

fileind contains the read FILEINDEX after successful return. must point to allocated, big enough memory.

4.57 store.c File Reference 383

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4168 of file store.c.

4.57.2.6 ReadSaveVariables()

```
WORD ReadSaveVariables (

UBYTE * buffer,

UBYTE * top,

LONG * size,

LONG * outsize,

INDEXENTRY * ind,

LONG * stage )
```

Reads the variables from the open file specified by AO.SaveData.Handle. It reads the *size bytes and writes them to the *buffer. It is called by PutInStore().

If translation is necessary, the data might shrink or grow in size, then *size is adjusted so that the reading and writing fits into the memory from the buffer to the top. The actual number of read bytes is returned in *size, the number of written bytes is returned in *outsize.

If the *size is smaller than the actual size of the variables, this function will be called several times and needs to remember the current position in the variable structure. The parameter *stage* does this job. When ReadSaveVariables() is called for the first time, this parameter should have the value -1.

The parameter ind is used to get the number of variables.

Parameters

buffer	read variables are written into this allocated memory	
top	upper end of allocated memory	
size	number of bytes to read. might return a smaller number of read bytes if translation was necessary	
outsize	if translation has be done, outsize contains the number of written bytes	
ind	pointer of INDEXENTRY for the current expression. read-only	
stage	should be -1 for the first call, will be increased by ReadSaveVariables to memorize the position in the	
	variable structure	

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 4354 of file store.c.

4.57.2.7 ReadSaveTerm32()

```
UBYTE * binend,
UBYTE ** bout,
UBYTE * boutend,
UBYTE * top,
int terminbuf )
```

Reads a single term from the given buffer at bin and write the translated term back to this buffer at bout.

ReadSaveTerm32() is currently the only instantiation of a ReadSaveTerm-function. It only deals with data that already has the correct endianness and that is resized to 32bit words but without being renumbered or translated in any other way. It uses the compress buffer AR.CompressBuffer.

The function is reentrant in order to cope with nested function arguments. It is called by ReadSaveExpression() and itself

The *return value* indicates the position in the input buffer up to which the data has already been successfully processed. The parameter *bout* returns the corresponding position in the output buffer.

Parameters

bin	start of the input buffer
binend	end of the input buffer
bout	as input points to the beginning of the output buffer, as output points behind the already translated data in the output buffer
boutend	end of already decompressed data in output buffer
top	end of output buffer
terminbuf	flag whether decompressed data is already in the output buffer. used in recursive calls

Returns

pointer to the next unprocessed data in the input buffer

Definition at line 4721 of file store.c.

4.57.2.8 ReadSaveExpression()

```
WORD ReadSaveExpression (

UBYTE * buffer,

UBYTE * top,

LONG * size,

LONG * outsize )
```

Reads an expression from the open file specified by AO.SaveData.Handle. The endianness flip and a resizing without renumbering is done in this function. Thereafter the buffer consists of chunks with a uniform maximal word size (32bit at the moment). The actual renumbering is then done by calling the function ReadSaveTerm32(). The result is returned in *buffer*.

If the translation at some point doesn't fit into the buffer anymore, the function returns and must be called again. In any case *size* returns the number of successfully read bytes, *outsize* returns the number of successfully written bytes, and the file will be positioned at the next byte after the successfully read data.

It is called by PutInStore().

Parameters

buffer	output buffer, holds the (translated) expression
top	end of buffer
size	number of read bytes
outsize	number of written bytes

Returns

= 0 everything okay, != 0 an error occurred

Definition at line 5131 of file store.c.

Functions

- STATIC_ASSERT (sizeof(STOREHEADER)==512)
- STATIC_ASSERT (sizeof(FILEINDEX)==512)

4.58.1 Detailed Description

Contains definitions for global structs.

!!!CAUTION!!! Changes in this file will most likely have consequences for the recovery mechanism (see checkpoint.c). You need to care for the code in checkpoint.c as well and modify the code there accordingly!

The marker [D] is used in comments in this file to mark pointers to which dynamically allocated memory is assigned by a call to malloc() during runtime (in contrast to pointers that point into already allocated memory). This information is especially helpful if one needs to know which pointers need to be freed (cf. checkpoint.c).

4.58.2 Macro Definition Documentation

4.58.2.1 INFILEINDEX

```
#define INFILEINDEX ((512-2*sizeof(POSITION))/sizeof(INDEXENTRY))
```

Maximum number of entries (struct InDeXeNtRy) in a file index (struct FiLeInDeX). Number is calculated such that the size of a file index is no more than 512 bytes.

Definition at line 119 of file structs.h.

4.58.2.2 EMPTYININDEX

```
#define EMPTYININDEX (512-2*sizeof(POSITION)-INFILEINDEX*sizeof(INDEXENTRY))
```

Number of empty filling bytes for a file index (struct FiLeInDeX). It is calculated such that the size of a file index is always 512 bytes.

Definition at line 124 of file structs.h.

4.58.3 Typedef Documentation

4.58.3.1 INDEXENTRY

```
typedef struct InDeXeNtRy INDEXENTRY
```

Defines the structure of an entry in a file index (see struct FiLeInDeX).

It represents one expression in the file.

4.58.3.2 FILEINDEX

```
typedef struct FiLeInDeX FILEINDEX
```

Defines the structure of a file index in store-files and save-files.

It contains several entries (see struct InDeXeNtRy) up to a maximum of INFILEINDEX.

The variable number has been made of type POSITION to avoid padding problems with some types of computers/

OS and keep system independence of the .sav files.

This struct is always 512 bytes long.

4.58.3.3 VARRENUM

```
typedef struct VaRrEnUm VARRENUM
```

Contains the pointers to an array in which a binary search will be performed.

4.58.3.4 RENUMBER

```
typedef struct ReNuMbEr * RENUMBER
```

Only symb.lo gets dynamically allocated. All other pointers points into this memory.

4.58.3.5 NAMENODE

```
typedef struct NaMeNode NAMENODE
```

The names of variables are kept in an array. Elements of type NAMENODE define a tree (that is kept balanced) that make it easy and fast to look for variables. See also NAMETREE.

4.58.3.6 NAMETREE

```
typedef struct NaMeTree NAMETREE
```

A struct of type NAMETREE controls a complete (balanced) tree of names for the compiler. The compiler maintains several of such trees and the system has been set up in such a way that one could define more of them if we ever want to work with local name spaces.

4.58.3.7 **COMPTREE**

```
typedef struct tree COMPTREE
```

The subexpressions in the compiler are kept track of in a (balanced) tree to reduce the need for subexpressions and hence save much space in large rhs expressions (like when we have xxxxxxx occurrences of objects like f(x+1,x+1) in which each x+1 becomes a subexpression. The struct that controls this tree is COMPTREE.

4.58.3.8 TABLES

```
typedef struct TaBlEs * TABLES
```

buffers, mm, flags, and prototype are always dynamically allocated, tablepointers only if needed (=0 if unallocated), boomlijst and argtail only for sparse tables.

Allocation is done for both the normal and the stub instance (spare), except for prototype and argtail which share memory.

4.58.3.9 FUNCTIONS

```
typedef struct FuNcTiOn * FUNCTIONS
```

Contains all information about a function. Also used for tables. It is used in the LIST elements of #AC.

4.58.3.10 FILEHANDLE

```
typedef struct FiLe FILEHANDLE
```

The type FILEHANDLE is the struct that controls all relevant information of a file, whether it is open or not. The file may even not yet exist. There is a system of caches (PObuffer) and as long as the information to be written still fits inside the cache the file may never be created. There are variables that can store information about different types of files, like scratch files or sort files. Depending on what is available in the system we may also have information about gzip compression (currently sort file only) or locks (TFORM).

4.58.3.11 STREAM

```
typedef struct StreaM STREAM
```

Input is read from 'streams' which are represented by objects of type STREAM. A stream can be a file, a do-loop, a procedure, the string value of a preprocessor variable When a new stream is opened we have to keep information about where to fall back in the parent stream to allow this to happen even in the middle of reading names etc as would be the case with a`i'b

4.58.3.12 TRACES

```
typedef struct TrAcEs TRACES
```

The struct TRACES keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue. The 4-dimensional traces are more complicated than the n-dimensional traces (see TRACEN) because of the extra tricks that can be used. They are responsible for the shorter final expressions.

4.58.3.13 TRACEN

```
typedef struct TrAcEn * TRACEN
```

The struct TRACEN keeps track of the progress during the expansion of a 4-dimensional trace. Each time a term gets generated the expansion tree continues in the next statement. When it returns it has to know where to continue.

4.58.3.14 PREVAR

```
typedef struct pReVaR PREVAR
```

An element of the type PREVAR is needed for each preprocessor variable.

4.58.3.15 DOLOOP

```
typedef struct DoLoOp DOLOOP
```

Each preprocessor do loop has a struct of type DOLOOP to keep track of all relevant parameters like where the beginning of the loop is, what the boundaries, increment and value of the loop parameter are, etc. Also we keep the whole loop inside a buffer of type PRELOAD

4.58.3.16 set_of_char

```
typedef struct bit_field set_of_char[32]
```

Used in set_in, set_set, set_del and set_sub.

Definition at line 145 of file structs.h.

4.58.3.17 one_byte

```
typedef struct bit_field* one_byte
```

Used in set_in, set_set, set_del and set_sub.

Definition at line 958 of file structs.h.

4.58.3.18 CBUF

```
typedef struct CbUf CBUF
```

The CBUF struct is used by the compiler. It is a compiler buffer of which since version 3.0 there can be many.

4.58.3.19 CHANNEL

```
typedef struct ChAnNeL CHANNEL
```

When we read input from text files we have to remember not only their handle but also their name. This is needed for error messages. Hence we call such a file a channel and reserve a struct of type CHANNEL to allow to lay this link.

4.58.3.20 NESTING

```
typedef struct NeStInG * NESTING
```

The NESTING struct is used when we enter the argument of functions and there is the possibility that we have to change something there. Because functions can be nested we have to keep track of all levels of functions in case we have to move the outer layers to make room for a larger function argument.

4.58.3.21 STORECACHE

```
typedef struct StOrEcAcHe * STORECACHE
```

The struct of type STORECACHE is used by a caching system for reading terms from stored expressions. Each thread should have its own system of caches.

4.58.3.22 PERM

```
typedef struct PeRmUtE PERM
```

The struct PERM is used to generate all permutations when the pattern matcher has to try to match (anti)symmetric functions.

4.58.3.23 PERMP

```
typedef struct PeRmUtEp PERMP
```

Like struct PERM but works with pointers.

4.58.3.24 **DISTRIBUTE**

```
typedef struct DiStRiBuTe DISTRIBUTE
```

The struct DISTRIBUTE is used to help the pattern matcher when matching antisymmetric tensors.

4.58.3.25 PARTI

```
typedef struct PaRtI PARTI
```

The struct PARTI is used to help determining whether a partition_function can be replaced.

4.58.3.26 SORTING

```
typedef struct sOrT SORTING
```

The struct SORTING is used to control a sort operation. It includes a small and a large buffer and arrays for keeping track of various stages of the (merge) sorts. Each sort level has its own struct and different levels can have different sizes for its arrays. Also different threads have their own set of SORTING structs.

4.58.3.27 ALLGLOBALS

```
typedef struct AllGlobals ALLGLOBALS
```

Without pthreads (FORM) the ALLGLOBALS struct has all the global variables

4.58.3.28 FIXEDGLOBALS

```
typedef struct FixedGlobals FIXEDGLOBALS
```

The FIXEDGLOBALS struct is an anachronism. It started as the struct with global variables that needed initialization. It contains the elements Operation and OperaFind which define a very early way of automatically jumping to the proper operation. We find the results of it in parts of the file opera.c Later operations were treated differently in a more transparent way. We never changed the existing code. The most important part is currently the cTable which is used intensively in the compiler.

4.59 symmetr.c File Reference

```
#include "form3.h"
```

Functions

4.60.1 Detailed Description

Contains all functions that deal with the table bases on the 'FORM level' The low level databse routines are in minos.c

4.61 threads.c File Reference

4.61.1 Detailed Description

Routines for the interface of FORM with the pthreads library

This is the main part of the parallelization of TFORM. It is important to also look in the files structs.h and variable.h because the treatment of the A and B structs is essential (these structs are used by means of the macros AM, AP, AC, AS, AR, AT, AN, AO and AX). Also the definitions and use of the macros BHEAD and PHEAD should be looked up.

The sources are set up in such a way that if WITHPTHREADS isn't defined there is no trace of pthread parallelization. The reason is that TFORM is far more memory hungry than sequential FORM.

Special attention should also go to the locks. The proper use of the locks is essential and determines whether TFORM can work at all. We use the LOCK/UNLOCK macros which are empty in the case of sequential FORM These locks are at many places in the source files when workers can interfere with each others data or with the data of the master.

4.62 token.c File Reference

```
#include "form3.h"
```

Macros

#define CHECKPOLY (if(polyflag)MesPrint("&lllegal use of polynomial function"); polyflag = 0; }

Functions

- int tokenize (UBYTE *in, WORD leftright)
- void WriteTokens (SBYTE *in)
- int simp1token (SBYTE *s)
- int simpwtoken (SBYTE *s)
- int simp2token (SBYTE *s)

4.63.1 Detailed Description

Low level routines for many types of task. There are routines for manipulating the input system (streams and files) routines for string manipulation, the memory allocation interface, and the clock. The last is the most sensitive to ports. In the past nearly every port to another OS or computer gave trouble. Nowadays it is slightly better but the poor POSIX compliance of LINUX again gave problems for the multithreaded version.

4.63.2 Macro Definition Documentation

4.63.2.1 TERMMEMSTARTNUM

#define TERMMEMSTARTNUM 16

Provides memory for one term (or one small polynomial) This means that the memory is limited to a buffer of size AM.MaxTer plus a few extra words. In parallel versions, each worker has its own memory pool.

The way we use the memory is by: term = TermMalloc(BHEAD0); and later we free it by TermFree(BHEAD term);

Layout: We have a list of available pointers to buffers: AT.TermMemHeap Its size is AT.TermMemMax We take from the top (indicated by AT.TermMemTop). When we run out of buffers we assign new ones (doubling the amount) and we have to extend the AT.TermMemHeap array. Important: There is no checking that the returned memory is legal, ie is memory that was handed out earlier.

Definition at line 2546 of file tools.c.

4.63 tools.c File Reference 399

4.63.2.2 NUMBERMEMSTARTNUM

```
#define NUMBERMEMSTARTNUM 16
```

Provides memory for one Long number This means that the memory is limited to a buffer of size AM.MaxTal In parallel versions, each worker has its own memory pool.

The way we use the memory is by: num = NumberMalloc(BHEAD0); Number = AT.NumberMemHeap[num]; and later we free it by NumberFree(BHEAD num);

Layout: We have a list of available pointers to buffers: AT.NumberMemHeap Its size is AT.NumberMemMax We take from the top (indicated by AT.NumberMemTop). When we run out of buffers we assign new ones (doubling the amount) and we have to extend the AT.NumberMemHeap array. Important: There is no checking on the returned memory!!!!

Definition at line 2646 of file tools.c.

4.63.2.3 DODOUBLE

```
#define DODOUBLE( x )
```

Value:

Definition at line 2969 of file tools.c.

4.63.2.4 DOEXPAND

```
#define DOEXPAND(
     x )
```

Value:

```
{ x *newbuffer, *t, *m;
t = newbuffer = (x *)Malloc1((newsize+2)*type, "ExpandBuffer");
if (*buffer) { m = (x *)*buffer; i = *oldsize;
while (--i >= 0) *t++ = *m++; M_free(*buffer, "ExpandBuffer");
} *buffer = newbuffer; *oldsize = newsize; }
```

Definition at line 2995 of file tools.c.

4.63.3 Function Documentation

4.63.3.1 CopyFile()

Copies a file with name *source to a file named *dest. The involved files must not be open. Returns non-zero if an error occurred. Uses if possible the combined large and small sorting buffers as cache.

Definition at line 1101 of file tools.c.

4.63.3.2 TimeWallClock()

```
LONG TimeWallClock ( \label{eq:word_par} \mbox{WORD } par \mbox{ )}
```

Returns the wall-clock time.

Parameters

par If zero, the wall-clock time will be reset to 0.

Returns

The wall-clock time in centiseconds.

Definition at line 3476 of file tools.c.

Referenced by DoCheckpoint().

4.63.3.3 TimeCPU()

```
LONG TimeCPU ( \label{eq:word_par} \text{WORD } par \ )
```

Returns the CPU time.

Parameters

par If zero, the CPU time will be reset to 0.

Returns

The CPU time in milliseconds.

Definition at line 3550 of file tools.c.

4.63.3.4 TestTerm()

```
int TestTerm ( \label{eq:word_word} \mbox{WORD} \; * \; term \; )
```

Tests the consistency of the term. Returns 0 when the term is OK. Any nonzero value is trouble. In the current version the testing isn't 100% complete. For instance, we don't check the validity of the symbols nor do we check the range of their powers. Etc. This should be extended when the need is there.

Parameters

Definition at line 3861 of file tools.c.

4.64 topowrap.cc File Reference

```
#include "form3.h"
#include "gentopo.h"
```

- #define VectorErases(X, index, n)

4.69.1 Detailed Description

An implementation of dynamic array.

Example:

```
size_t i;
Vector(int, vec);
VectorPushBack(vec, 1);
VectorPushBack(vec, 2);
VectorPushBack(vec, 3);
for ( i = 0; i < VectorSize(vec); i++ )
  printf("%d\n", VectorPtr(vec)[i]);</pre>
VectorFree (vec);
```

4.69.2 Macro Definition Documentation

4.69.2.1 VectorStruct

```
#define VectorStruct(
              T)
Value:
   struct { \
       T *ptr; \
       size_t size; \
       size_t capacity; \
```

A struct for vector objects.

Parameters

```
T the type of elements.
```

Definition at line 65 of file vector.h.

4.69.2.2 Vector

Defines and initialises a vector X of the type T. The user must call VectorFree(X) after the use of X.

Parameters

T	the type of elements.
X	the name of vector object

Definition at line 84 of file vector.h.

4.69.2.3 DeclareVector

Declares a vector X of the type T. The user must call $\operatorname{VectorInit}(X)$ before the use of X.

Parameters

T	the type of elements.
X	the name of vector object

Definition at line 99 of file vector.h.

4.69.2.4 VectorInit

```
\begin{tabular}{ll} \# define & VectorInit( & X \end{tabular} \label{eq:continuous}
```

Value:

```
do { \
       (X).ptr = NULL; \
(X).size = 0; \
(X).capacity = 0; \
} while (0)
```

Initialises a vector X of the type T. The user must call VectorFree(X) after the use of X.

Parameters

```
Χ
    the vector object.
```

Definition at line 113 of file vector.h.

4.69.2.5 VectorFree

```
#define VectorFree(
                           X )
Value:
      do {
    M_free((X).ptr, "VectorFree:" #X);
    (X).ptr = NULL;
    (X).size = 0;
    (X).capacity = 0;
}
```

Frees the buffer allocated by the vector X.

Parameters

```
the vector object.
```

} while (0)

Definition at line 130 of file vector.h.

4.69.2.6 VectorPtr

```
#define VectorPtr(
             X ) ((X).ptr)
```

Returns the pointer to the buffer for the vector X. NULL when VectorCapacity(X) == 0.

Parameters

```
X \mid the vector object.
```

Returns

the pointer to the allocated buffer for the vector.

Definition at line 150 of file vector.h.

4.69.2.7 VectorFront

Returns the first element of the vector X. Undefined when VectorSize(X) == 0.

Parameters

Returns

the first element of the vector.

Definition at line 165 of file vector.h.

4.69.2.8 VectorBack

```
\label{eq:define VectorBack} \begin{tabular}{ll} $X$ & ((X).ptr[(X).size - 1]) \end{tabular}
```

Returns the last element of the vector X. Undefined when VectorSize(X) == 0.

Parameters

Returns

the last element of the vector.

Definition at line 180 of file vector.h.

4.69.2.9 VectorSize

```
#define VectorSize( X ) ((X).size)
```

Returns the size of the vector X.

Parameters

```
X the vector object.
```

Returns

the size of the vetor.

Definition at line 194 of file vector.h.

4.69.2.10 VectorCapacity

```
\begin{tabular}{ll} \# define \ Vector Capacity ( & X ) & ((X).capacity) \end{tabular}
```

Returns the capacity (the number of the already allocated elements) of the vector X.

Parameters

Returns

the capacity of the vetor.

Definition at line 208 of file vector.h.

4.69.2.11 VectorEmpty

```
#define VectorEmpty( X ) ((X).size == 0)
```

Returns true the size of the vector X is zero.

Parameters

Returns

true if the vector has no elements, false otherwise.

Definition at line 222 of file vector.h.

4.69.2.12 VectorClear

```
#define VectorClear( X ) do { (X).size = 0; } while (0)
```

Sets the size of the vector X to zero.

Parameters

```
X the vector object.
```

Definition at line 235 of file vector.h.

4.69.2.13 VectorReserve

```
#define VectorReserve( \it X, \it newcapacity)
```

Value:

Requires that the capacity of the vector X is equal to or lager than newcapacity.

Parameters

X	the vector object.
newcapacity	the capacity to be reserved.

Definition at line 249 of file vector.h.

4.69.2.14 VectorPushBack

```
#define VectorPushBack( X, x )
```

Value:

```
do { \
     VectorReserve((X), (X).size + 1); \
     (X).ptr[(X).size++] = (X); \
} while (0)
```

Adds an element x at the end of the vector X.

Parameters

X	the vector object.	
X	the element to be added.	

Definition at line 277 of file vector.h.

4.69.2.15 VectorPushBacks

```
#define VectorPushBacks( X, src, n )
```

Value:

```
do {
    size_t v_tmp_n_ = (n);
    VectorReserve((X), (X).size + v_tmp_n_);
    memcpy((X).ptr + (X).size, (src), v_tmp_n_ * sizeof((X).ptr[0]));
    (X).size += v_tmp_n;
} while (0)
```

Adds an n elements of src at the end of the vector X.

Parameters

X	the vector object.
src	the starting address of the buffer storing elements to be added.
n	the number of elements to be added.

Definition at line 295 of file vector.h.

4.69.2.16 VectorPopBack

```
#define VectorPopBack( X ) do { (X).size --; } while (0)
```

Removes the last element of the vector X. VectorSize(X) must be > 0.

Parameters

```
X the vector object.
```

Definition at line 314 of file vector.h.

4.69.2.17 VectorInsert

Inserts an element x at the specified index of the vector X. The index must be $0 \le$ index < VectorSize(X).

Parameters

X	the vector object.
index	the position at which the element will be inserted.
X	the element to be inserted.

Definition at line 330 of file vector.h.

4.69.2.18 VectorInserts

Value:

```
do {
    size_t v_tmp_index_ = (index), v_tmp_n_ = (n); \
    VectorReserve((X), (X).size + v_tmp_n_); \
    memmove((X).ptr + v_tmp_index_ + v_tmp_n_, (X).ptr + v_tmp_index_, ((X).size - v_tmp_index_) *
    sizeof((X).ptr[0])); \
    memcpy((X).ptr + v_tmp_index_, (src), v_tmp_n_ * sizeof((X).ptr[0])); \
    ((X).size + v_tmp_n_; \
} while (0)
```

Inserts an n elements of src at the specified index of the vector X. The index must be 0 <= index < VectorSize(X).

Parameters

X	the vector object.
index	the position at which the elements will be inserted.
src	the starting address of the buffer storing elements to be inserted.
n	the number of elements to be inserted.

Definition at line 353 of file vector.h.

4.69.2.19 VectorErase

```
#define VectorErase( X, index )
```

Value:

```
do {
    size_t v_tmp_index_ = (index); \
    memmove((X).ptr + v_tmp_index_, (X).ptr + v_tmp_index_ + 1, ((X).size - v_tmp_index_ - 1) *
    sizeof((X).ptr[0])); \
    (X).size--; \
} while (0)
```

Removes an element at the specified index of the vector X. The index must be $0 \le$ index < VectorSize(X).

Parameters

X	the vector object.
index	the position of the element to be removed.

Definition at line 374 of file vector.h.

4.69.2.20 VectorErases

Value:

```
do {
    size_t v_tmp_index_ = (index), v_tmp_n_ = (n); \
    memmove((X).ptr + v_tmp_index_, (X).ptr + v_tmp_index_ + v_tmp_n_, ((X).size - v_tmp_index_ - 1) *
    sizeof((X).ptr[0])); \
    (X).size -= v_tmp_n_; \
} while (0)
```

Removes an n elements at the specified index of the vector X. The index must be $0 \le index < VectorSize(X) - n + 1$.

Parameters

X	the vector object.	
index	the starting position of the elements to be removed.	
n	the number of elements to be removed.	

Definition at line 394 of file vector.h.

4.70 wildcard.c File Reference

#include "form3.h"

Macros

• #define **DEBUG**(x)

Functions

- WORD WildFill (PHEAD WORD *to, WORD *from, WORD *sub)
- WORD ResolveSet (PHEAD WORD *from, WORD *to, WORD *subs)
- VOID ClearWild (PHEAD0)
- WORD AddWild (PHEAD WORD oldnumber, WORD type, WORD newnumber)
- WORD CheckWild (PHEAD WORD oldnumber, WORD type, WORD newnumber, WORD *newval)
- int **DenToFunction** (WORD *term, WORD numfun)

4.70.1 Detailed Description

Contains the functions that deal with the wildcards. During the pattern matching there are two steps: 1: check that a wildcard substitution is correct (if there was already an assignment for this variable, it is the same; it is part of the proper set; it is the proper type of variables, etc.) 2: make the assignment In addition we have to be able to clear assignments. During execution we have to make the actual replacements (WildFill)
